AMERICAN JOURNAL OF PSYCHIATRY

INFORMATION FOR CONTRIBUTORS

Manuscripts—The *original* manuscripts of papers read at the annual meetings of the Association should be deposited with the Secretary during the meetings, or sent to the New York office promptly afterward. Do not deposit carbon copies.

Papers read at the annual meetings become the property of the Association. Not all papers read, however, can be published in the JOURNAL, and authors wishing to publish in other vehicles will first secure from the Editor the release of their manuscripts.

Papers will not be accepted for the annual program if they have been previously read at other meetings or if they have been already published.

Papers contributed during the year (not on the annual program) should be sent to the Editor, Dr. Clarence B. Farrar, 216 St. Clair Avenue West, Toronto 5, Ontario, Canada.

Style—Manuscripts should be typewritten, double spaced, on one side of paper. They must be prepared in conformity with the general style of The American Journal of Psychiatry. Retain a carbon copy of manuscript and duplicates of tables, figures, etc., for use should the originals be lost in the mails.

Multiple Authorship—The number of names listed as authors should be kept to a minimum, others collaborating being shown in a footnote.

Illustrations—Authors will be asked to meet printer's costs of reproducing illustrative material. Copy for illustrations cannot be accepted unless properly prepared for reproductions. Wherever possible, drawings and charts should be made with India ink for photographic reproduction as zinc etchings. Photographs for halftone reproduction should be glossy prints. Illustrations should be as small as possible without sacrificing important detail. Redrawing or preparing illustrations to make them suitable for photographic reproduction will be charged to author.

Authors' Corrections in Proofs—Corrections, additions or deletions made by authors are to be charged to them. These alterations are charged on a time basis at the rate of \$3.00 per hour. Proper editing of original manuscript is important to avoid the expense of correction.

Tables—Tables should be typed and on separate sheets. Tables are much more expensive to set than text material and should be used only where necessary to clarify important points. Authors will be asked to defray cost of excessive tabular material.

References—References should be assembled according to author in a terminal bibliography, referred to in text by numbers in parentheses. Bibliographical material should be typed in accordance with the following style for journals and books respectively:

1. Vander Veer, A. H., and Reese, H. H. *Am. J. Psychiat.*, 95: 271, Sept. 1938.
2. Hess, W. R. *Diencephalon*. New York: Grune & Stratton, 1954.

Abbreviations should conform to the style used in the Quarterly Cumulative Index Medicus.

The American Journal of Psychiatry, formerly The American Journal of Insanity, the official organ of The American Psychiatric Association, was founded in 1844. It is published monthly, the volumes beginning with the July number.

The subscription rates are \$12.00 to the volume: Canadian subscriptions, \$12.50; foreign subscriptions, \$13.00, including postage. Rates to medical students, junior and senior internes, residents in training during their first, second, or third training year, and also to graduate students in psychology, psychiatric social work, and psychiatric nursing, \$5.00 (Canada \$5.50). Single issues, \$1.25.

Copyright 1956 by The American Psychiatric Association
Office of Publication, 1601 Edison Highway, Baltimore 13, Md.

Editorial communications, books for review, and exchanges should be addressed to the Editor, Dr. Clarence B. Farrar, 216 St. Clair Avenue West, Toronto 5, Ontario, Canada.

Business communications, remittances and subscriptions should be addressed to The American Psychiatric Association, 1601 Edison Highway, Baltimore 13, Md., or to 1270 Avenue of the Americas, New York 20, N. Y.

Entered as second class matter July 31, 1911, at the post office at Baltimore, Maryland, under the Act of March 3, 1879. Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917. Authorized on July 3, 1918.

PSYCHIATRY AND THE SCIENCE OF MAN¹

FRANCIS J. BRACELAND, M.D.

We are that bold and adventurous piece of nature, which he that studies may wisely learn, in a compendium, what others labour at in a divided piece and endless volume.

SIR THOMAS BROWNE

FOREWORD

I

Just as there is no longer a place by the fireside for grandfather to sit and smoke his pipe, so there is really no room for the president of this group to give a report on the state of affairs of the Association. This is no complaint—he can do it, of course, but it is done so much better now by the administrative officers and by the various chairmen that another report would be redundant.

I shall not try to express my thanks to you; I would make a bad job of it. You know how I feel upon receipt of this, the highest honor you have to confer. To the officers and the various staffs I shall express my thanks privately and clumsily, I am sure. To paraphrase Mr. Churchill, never has any one man been indebted to so many for so much. I return this office to you with humility and affection and the hope that I have guarded it well.

Along with the reportorial function, another door is now closed to the president of the Association. Everyone, who has followed his peregrinations in the News Letter, knows that he has had little time for research—yea, even little time for clinical observation—while he rushed from hearing to meeting, and from trains to planes. And yet, by hallowed custom, a discourse is required of him as he turns over his badge of office. There is only one path open to him then—the philosophic. He can examine the status of the discipline and see how it fares in relationship to its sister specialties and to art and science in general. This I shall do and shall examine our relationship to the science of man, for it is time now to consider the location of our art and science in space and perhaps to scan the horizon and attempt to determine the directions which our specialty is taking.

When the theoretical physicists, Doctors Lee and Yang, recently challenged the principle of parity, their work shattered completely one of the basic laws which had been built into all physical theories in the past thirty years. This had been a philosophically pleasing theory—this idea of mirror symmetry of submicroscopic particles—which they demolished and, worse and more of it, it had consistently borne fruit in the making of successful predictions about atomic and nuclear processes. This is worthy of our attention—the theory was erroneous; yet successful predictions were made from it. Now, suddenly, this attractive theory was destroyed and we are told that there is no one who can say when or how the pieces will be put together again. In the early stages of their work, the young scientists could hardly have suspected the widespread implications their findings would have, but before long it became apparent that an obstacle was removed and a way was now clear and, out of the intellectual ferment and ceaseless reexamination of principles the new discovery had initiated, there might eventuate something which thus far had eluded all scientists. This eventuality hopefully might be a unified field theory encompassing all of the laws of matter, energy and the universe.

This little drama of physical science had its counterpart in the last decade of the last century when Freud challenged the then current ideas regarding the etiology of emotional disorder. These ideas, too, had been philosophically comfortable and they had been held in various guises for many years. Freud's brilliant observations, unrecognized and unappreciated at first, are now seen to have signalled a turning point, not only in psychology, but also in science, and from them another eventuality might also stem—in this case a step toward a unitary or inte-

¹ Presidential Address delivered at the 113th annual convention of The American Psychiatric Association, May 13-18, 1957, Chicago, Ill.

grated approach to the science of man. Some aspects of the new theory, as propounded first, would have to be changed, but even from these would come some successful predictions about the emotional reaction of man.

While the potentialities of the physicists' ideas were recognized quickly, Freud's revolutionary ideas were missed entirely. They were even overlooked by Freud and his colleagues, for they did not realize that here were the precursors of an entirely new system of thought, one which would require an approach entirely different from that being applied to the formulations of general medicine. Unhappily, this new system was forced into the then extant and waiting molds of scientific thought, though it took procrustean techniques to do it. Had the newness and the significance of these ideas been recognized and had they been followed to their logical conclusion, instead of being pushed into convenient molds, much of the bitterness and opposition which their promulgation engendered would have been avoided. It is only now that the far reaching importance of these ideas and insights are being fully appreciated. Their influence penetrates into many disciplines; they are more by far than a treatment and research method; buried in them are precious creative currents and, in the words of Karl Stern,² as a result of what we have learned from them, "our image of the interior world of man can never be the same as it was prior to 1894."

The beginnings of a new era are usually not recognized by the pioneers who are working in it. Ordinarily they proceed, thinking and operating in the approved categories of the time, unaware of the revolutionary aspects of their work. It was ever thus. It is the historian who retrospectively sees indications of approaching revolution at a time when few are aware that their traditional world is in rapid change. Though it may seem paradoxical in the light of some present day teaching, viewed in the light of history this new psychology heralded the end of a purely mechanistic concept of man.

Once again, as we meet here today, there are omens and portents which indicate that we are on the threshold of other major

changes. The tell-tale symptoms and signs are those of restless inquiry, examination and reexamination. Many of the major medical disciplines are in a state of transition, as are the physical sciences. The Joint Commission on Mental Health is about its important comprehensive investigations. Psychoanalysis is examining itself as a discipline and seeking to evaluate its efforts and its results and its directions, and one might prognosticate that the findings will herald an even closer rapprochement with medicine.

Medical educators are in full scale reassessment of their curricula, due to the realization that, despite their high standards, something is still lacking in their finished product. The practice of medicine itself is changing and, as Atchley³ puts it, the doctor now, "instead of being satisfied to merely identify his patient's condition with a large group of similar diseases, tries to analyze all the various abnormal components in this one person and thus reach an appraisal, rather than apply a label."

Verily, then, these are times of change—these are the best of times; these are the worst of times—we have everything before us; we have nothing before us. There are sounds of trouble in the distance, but the click of Madame Defarge's needles now is supplanted by the sound of the Geiger counter symbolic of a nuclear age. In this transitional phase, as psychiatry reexamines itself, it seeks to find its place in the scheme of things. Until now it has been lusty, sprawling, verbose and growing apace. It is wise to examine itself while there is still an earth for the meek to inherit.

If the present state of psychiatry is envisaged as one of transition or transformation, there arise certain problems of gravity which the psychiatrist has to consider in full consciousness of his responsibility and hence, in seriousness and humility. The future development of his discipline depends upon the solution of these problems, as does the value of the services he will render to mankind. Though philosophers may discuss whether the events of history follow their own intrinsic, inexorable laws, or whether they be directed to some extent by man's doings, we

² The Third Revolution. Karl Stern, Harcourt Brace & Co., N. Y.

³ The Changing Physician. Dana W. Atchley, The Atlantic Monthly, Aug. 1956.

must act, as Ignatius Loyola says, as if everything depended upon us, even though we know that nothing depends upon us alone.

Modern psychiatry, by virtue of its intrinsic developments on the one hand, and by the demands made by society on the other, differs from what it was even a quarter century ago. It no longer focuses entirely upon mental disease, nor the individual as a "mental patient," but rather it envisages man in the totality of his being and in the totality of his relationships. Consequently, the place of psychiatry within the system of medicine, as well as within the complex of all disciplines concerned with man, his nature, his work and his destiny, also has changed. If one designates the totality of all disciplines concerned with the manifold aspects of human being and doing as *humanism*, then psychiatry has become a *humanistic* discipline. It has become an essential part of an over-all science of man—of general anthropology. The movement of psychiatry in this direction and the ensuing transformation of psychiatric thinking is not an isolated phenomenon. It is expressive of a new turn in the manner in which man looks at himself. It was Sherrington who said: "Man in his mood may count himself in his day a brief spectator of his own shaping as it still progresses."

Psychiatry by becoming more humanistic need not in any way become less scientific. Scientific inquiry and methodology must always form the solid foundation of our discipline, but upon this foundation must be erected the edifice of a psychiatry which will be an applied science of man. The humanistic tendencies of our discipline have already proved a stumbling block for some of our medical colleagues. Because of some misunderstanding, they equate the humanistic aspects of our approach with a meddlesome form of do-goodism; yet nothing can be further from the truth. Humanism and a scientific approach to the science of man are not mutually exclusive. By science we mean here not mathematical science in the narrow sense of the term, but the meaning which it had of old: "encompassing and well ordered knowledge." One might even say the ideal goal of the psychiatrist is to achieve wisdom. The best one can do, of course, is to aspire to this attainment and the first step toward

it is that of recognizing one's limitations, of being conscious, as was Socrates, that one knows nothing in comparison with what he should know. Psychiatry can be justly proud of its achievements in the relatively short time in which it has functioned as a discipline; yet at the same time it is required to be humble because of what it does not know and because of the enormous problems which still face it. Paradoxically, wisdom is a mixture of humility and legitimate pride.

If psychiatry is to take its proper place in the science of man, it must be aware of its limitations and realize that it is only a part of this science, an important but a small part insofar as the general knowledge of man is concerned. To forget this is to run the danger of scientific imperialism. By this term I mean to indicate the tendency, encountered regularly in the history of knowledge, to credit a special discipline with universal significance. The final result of such enthronement is always the catastrophic dethronement of the apparently supreme branch of knowledge. You have seen this little melodrama even within the framework of psychiatry itself. If you cast about you, you will see it on an even larger scale in the form of a cloud of anti-scientific attitude, "no bigger than a man's hand," but there nonetheless. It is an increasing unwillingness to see in science a world-saving panacea or to believe in the possibility of solving all human problems by means of scientific inquiry. If this cloud enlarges, it is because the scientists, or perhaps better the popularizers of science, have indulged in this imperialism and failed to recognize that human existence shows facets where science and her methodology prove insufficient. The same danger faces psychiatry, if its popularizers become too enthusiastic or its enthusiasts become too popular.

We would indeed lose many of our gains if we were injudicious enough to inflate the importance of our discipline in human affairs. There is at times a strong temptation to do this, as various questioners flatter us into making statements beyond our competence. Our specialty might have been put in a ludicrous light by some enthusiasts immediately after World War II. Do you remember the reductionism in the concepts and the arrogance with which they were to be applied?

The paradigm was simple—the proponents were flush with remembrance of recent accomplishment and recent victory. The reasoning went something like this: Fights and wars are caused by hostility in men. We understand and treat hostility. We shall do this on a large scale. Ergo, we will stop wars. Do you remember that chauvinism? Fortunately, wiser heads prevailed or it might have been dangerous. We spoke above of our need for humility and wisdom and now we see the need to add prudence to these virtues.

We must beware of attempting to derive universal principles or rules for a general science of man from our limited observations. It is necessary for us to keep in mind the fact that we deal with one group of human beings and with reactions in some way abnormal. It is wise to remember also that the study of the abnormal indeed posits the question of what is normal, but it does not necessarily answer it.

Psychiatry is a part of the science of man; it has a place in it and is a dependent upon it and a contributor to it. It is a part of the science of man because it deals with certain basic and historic problems of man and his society: with thought, emotion, behavior and human relatedness gone wrong. Psychiatry is dependent upon that science, inasmuch as appraisal of the abnormal is necessarily based upon knowledge of what is conceded to be normal, on knowledge of man's intrinsic nature and what makes him function and behave as he does. Psychiatry's contribution comes from the demonstration it makes of certain basic features of the human psyche and their universality.

II

Science builds upon knowledge previously accumulated, not only in its own field, but in encompassing and contiguous areas. All inquiry in a circumscribed area is advantaged by the use of general principles and the data of related sciences. Psychiatry is dependent upon many disciplines concerned with human biology and human behavior. Just as the phenomenon, man, and all that pertains to it is extremely complex, so also is abnormality at the human level. The more abnormality refers to the total human being, as it does in psychiatry, the more necessary it becomes for

psychiatry to consider all of the diverse aspects of human nature and human conduct and to examine the knowledge recorded by succeeding generations of thoughtful students of man. We learn today what we may have to unlearn tomorrow and we learn recurrently lessons which were taught before and then forgotten in the changing seasons of science. Today the accumulation of knowledge about man and his behavior is proceeding swiftly along many fronts and from the interpenetration and integration of that knowledge will emerge the new science of man of which we speak. It will be well for us to incorporate into that science the older wisdom and not to neglect it because it speaks of man's eternal preoccupations and so of his future purpose.

Speculative as this all may seem, it is of the greatest importance to us here and now. The organic substrate of the psyche is again a matter of major interest and, if we are not careful, all or part of that vast psychological insight, which Janet, Freud, Jung, Adler and Meyer and their followers gave us, will languish or be minimized. We have already hinted at the dangers of reductionism from the complex phenomena with which we deal to any simple formula. The history of psychiatry which reflects the cultural, as well as the medical, climate of society is testimony to this. Exclusively mentalistic and exclusively biological conceptions have reigned in turn and have contributed in turn to the one-sidedness of psychiatry's preoccupation at various recurring intervals. The pendulum has swung widely—too widely—from one extreme to the other and this has boded ill for our specialty.

Very broadly speaking and with more simplification than is at all justifiable, one may follow three great periods in the history of mental disorder. One is predominantly mentalistic, in the middle ages, when mental disturbances were seen as the outcome of inordinate living or as an index of demonic possession. Yet, mental diseases were certainly recognized as illnesses before that time. William of Paris (Died 1242) noted that physicians did not know enough of diseases of the mind. His voluminous treatise, *De Universo*, includes some peculiar ideas concerning the functions of the brain which stem partly from Aristotle (i.e., the notion of the

brain as a "cooling organ" and of the heart as the seat of mental operation may be found in several of his works), and partly from the latter's Arabian commentators, especially Avicenna. These notions were further developed by Thomas Aquinas in the 13th century, leading logically to the doctrine that certain mental disorders could, or even must, be caused by disturbances of cerebral function. Similar ideas could be traced back even to a follower of Pythagoras, Alcmaeon of Croton, in Southern Italy in the 6th century B. C. It is noteworthy also that in the medical school at Salerno the central role of the nervous system was taught in the 12th century and that they recognized the left-right relationships of the hemispheres and the body. Yet, with all of this, there was a swing to the mentalistic and medicine abjured its responsibility for patients with psychic deviations. There resulted a constant pyramiding of superstition and cruelties that marked much of society's dealing with the mentally ill up to the 19th century.

Although Pinel is justly famous for his humanitarian efforts with the mentally ill and for paving the way for a psychology with strong ethical connotations, he also did something else which was to have major repercussions throughout medicine. In his *Nosographie Philosophique*, published in 1798, he attempted to apply to problems of disease a new method of scientific analysis inspired by the Linnean system of scientific classification, and also by the philosophy of the enlightenment. However, Pinel came under the doubtful influence of such philosophers as Condillac and LeMettrie, the latter himself a physician and the man who coined the term, "man, the machine." This period, with a short interruption during the age of Romanticism, culminated in the formula: *mental diseases are brain diseases*. It was the period of a more or less fantastic brain mythology in which the current psychological conceptions were restated, via arbitrary and superficial analogies, in terms of hypothetical cerebral functions. The moral connotations of psychology went into complete eclipse and the way was open for an investigation of man's mental processes on purely mechanistic levels. Here, indeed, was a wide swing of the pendulum.

Charcot, who had such a decisive influence

on the formal development of neurology and neuropathology in the latter 19th century, was also instrumental in pointing the way to psychogenetic concepts in psychiatry. The struggle was bitter in that climate of the time, which considered scientific only the biological approach to man and man's diseases and in which the evolutionary theory was used to explain whole systems of philosophy, psychology and sociology. It was natural and expedient to effect a compromise, if possible, between biological and psychological notions. Freud accomplished this by making psyche and soma two closely related aspects of the living human organism. Instinct is thus rooted in bodily functions and apparatus and also represented in the mind by the image of the situation which would afford instinctual satisfaction, either directly or indirectly. In this way it was possible to view mental states and experiences as causal determinants without relinquishing the idea that everything in man is ultimately organic or somatic. Few authorities took kindly to this compromise, particularly when Freud also tried to show that the psyche has its reasons that reason knows not of, and when his use of the symbol made it possible to extend the range of psychogenesis to bodily symptoms. However, powerful adherents gradually flocked to the psychoanalytic banner and it transpired, in some way contrary to the original spirit of the Freudian doctrine, that exclusive emphasis was placed upon psychogenesis and the somatic aspects of mental disorder were neglected. The pendulum had swung widely again.

We noted earlier that this new psychology brought with it an entirely new view of man's nature. Symptoms were considered expressions of the total personality; inquiry was directed at the hidden purposiveness of neurotic phenomena and the meaningfulness of experience was construed to depend upon the individual, his life history, attitudes and value systems. This emphasis was revolutionary and might have had more ready acceptance had it been kept from the old mold of cause and effect relationships, which followed the laws of thermodynamics presumed to apply to a closed energy system. Like the principle of parity, such a system permitted many successful predictions but that it would need to be tempered became apparent as vari-

ous physical methods of treatment appeared and made possible definite therapeutic progress. Not that the value of psychotherapy was lessened in any way, but it became clear and definite, and we now may regard it as axiomatic that *no one approach to psychiatric disorder can claim a monopoly upon wisdom, understanding or therapeutic efficacy.*

III

It is evident by now that we espouse a comprehensive form of psychiatry and that integration is the watch word in our emphasis. Unfortunately, this term has taken on connotations which are not our consideration here. By integration we mean that all possible aspects of man's make-up and his needs be considered and united with each other in a homogeneous picture. Having discussed the predominantly mental, we should note briefly the activities in the somatic and the social aspects of man's life and what, for want of a better term, we will designate the philosophy of present day existence. This is the material with which, and the field in which the psychiatrist works. As we consider the various activities in the neurological sciences, we see some new formulations which hint at some old ideas.

We do not need to touch upon the new drugs in this discussion, for we can be sure they will receive thorough consideration at this meeting. You all know their attributes and their deficiencies. We can be properly thankful for the appearance of these potent agents, and at the same time hope that in the light of our past experiences we will not be tempted into an era of uncritical pharmaceutical enthusiasm. Perhaps the best antidote against this would be the required reading and rereading of Stewart Wolf's excellent work on Placebos. The description therein of the man who had asthma for 27 years and who responded to the new drug administered under carefully controlled conditions, only to have it later prove to be an inert substance, should furnish the theme for meditation for all those whose chemical titer gets out of bounds.

Likewise, we shall not discuss those substances which have produced psychotic-like experiences in the normal individual. There

is hope that out of this work will emerge some new insights.

In the meantime, the biological sciences have also been evolving approaches to a more integrated conception of man. Paralleling the studies of interpersonal relations by psychiatrists, neurophysiologists have studied the communications functions of the nervous system. Some psychiatric and neurophysiological positions purport to see certain analogues between man and the newer machines. This analogy, of course, has decided limitation and recalls to us the difficulties of Pinel's time with the concept, man, the machine. Men are not tools nor parts of a mechanism which functions the better the more appropriate the choice of its constituent elements.

In the area of man's biological needs, neurological experiments over the past decade have demonstrated a mechanism, lying in the internal core of the central nervous system, which is especially concerned in the regulation of biological adjustments. Some parts of this mechanism had previously been exposed by Claude Bernard and by Cannon, Bard, Rioch and others. But this work has been amplified to show osmosensitivity and pharmacosensitivity of the midline periventricular structures. In addition, there has been uncovered by Magoun a diffuse, afferent mechanism sensitive to the total amount of external stimulation—a mechanism involved in regulations of sleep and wakefulness and in the facilitation or inhibition of every sort of organismic activity. It is a mechanism which may well be responsible for the phenomenon observed by Spitz and others, that the amount of total stimulation during early infancy has an important influence on normal development.

There is evidence that the multiple determination of behavior is the outstanding "evolutionary" trend correlated with the development of the forebrain, and especially of the cerebral cortex. Experimental results suggest that the internal portions of the forebrain (the rhinencephalon, some of the basal nuclei and the septal region) have a bearing on motivation of behavior from the standpoint of reward and punishment. Foreseeing the outcomes of actions seems to be intimately bound to the relation between the frontal cortex, the limbic systems and the

hypothalamus. Recent experimental work by Pribram further elaborates fronto-cortical functions, in the sense that frontal lesions seem to affect the relative expectation placed on the desirability (rewarding or punishing aspect) of an action's outcome. Such expectation is determined by many factors apart from the biological "demands" of the organism, including the environmental "supply" of possible outcomes. These findings suggest to Pribram that, in an overall comprehension of man's being, that aspect which concerns man as a communicating organism from both psychiatric and neurophysiological points of view needs to be supplemented by the conception of man as an "economic" being, as one who not only communicates knowledge but is also capable of wisdom—capable, as he puts it, of "equilibrating expectations of the desirability of the outcomes of actions." Thus, at his social best, man is ethical and thus, also, from new experiments come suggestions of old ideas.

We have, therefore, from clinical psychiatry, as well as from experimental and neurophysiological sciences affirmations that the various aspects of human existence and nature interpenetrate each other, for the so-called lower layers are indispensable for the functioning of the higher, and the latter govern to an important degree the operation of the lower echelons. The data of the strictly vital vegetative and sensory functions are elaborated in higher mental operation and the composite influences, and are modified in turn by the social aspects of man and his relationships with his fellows. But none of this is independent from, or immune to what we may call man's higher aspirations, the meaning of his life, his understanding of himself and his place in the order of things. The net result of the evidence we have underscores the need to approach psychological problems from the humanistic point of view which affirms man's spiritual nature.

Meaningfulness of existence is not a by-product of modern science. Science produces no antidote for the trials and tribulations of man in a changing social and industrial order and a rapidly diminishing world. Man is easily upset and thrown off balance when the things on which he habitually relies fail him. The quest for security in modern life is diffi-

cult of attainment. For every new security established, another insecurity emerges. Not only does technological development bring its own dangers, but maintenance of security depends on ever closer cooperation and a denser network of social relationships. The more complicated a machinery becomes, the more vulnerable it becomes, and this is certainly true of the machinery of social life, and it is within the bounds of this social life that the psychiatrist works.

Today's society is seemingly dominated by what Riesman calls the "other-directed" man, who finds the motivations of his conduct and the ends he pursues not in himself, but in the dictation of the group. An age of mass production and mass communication gives birth to a mass society, where the individual is as much standardized as are syndicated columns, TV shows and the products of industry. Few dare to be different, and for good reason—for to be different brings them under the condemnation of the group on whose opinion they form their own opinion of themselves. The idolatry of conformity, of being exactly like everyone else in a group which tolerates only "marginal diversity"; the frenzy with which so many people addict themselves to all sorts of superficial activities or passivities—these and other enslavements of contemporary life originate, at least to some extent, from the need to replace beliefs and values and faith in which man once found security. But man's dignity cannot be served in ways that tend to depersonalize him and to deprive his existence of its real meaning. It cannot be served in the "over-adjustment" which is being advocated today, and the attempt to fit all men into a common denominator: the cooperative submitting member of the group.

Sooner or later it dawns on at least some of the people assimilated into modern mass society that their lives are empty of meaning; consequently that they themselves mean little; hence that quiet depression so often encountered in the hearts of men. Though man is conscious, if only in the hidden depths of his being, that he is a unique individual and irreplaceable, modern life makes each individual replaceable and denies his intrinsic and unquenchable need of being himself rather than a mere representative of a uni-

versal type. All one-sided development easily becomes pathological and may be pathogenic. That the more gregarious man becomes, the more he attains to the "good life," is a widely held misconception. Participation in culture is not the same as blindly adjusting to the group and submitting to its tyranny. Nor is the group, as such, necessarily representative of a "cause." On the contrary, we see today a marked aversion of average groups to be engaged in a cause; it is the fringe group, the contentious and litigious, which so often noisily espouses the causes, particularly if they are against something, or if they light up the unconscious hostilities or prejudices of the chronic querulant.

To serve man's dignity means to consider each man's individuality thoroughly and widely. The necessity of viewing man by means of categories of "historical thinking" is as obvious here as it ever was in the development of new approaches to psychiatry in recent years. These new approaches tend to make both the study and practice of psychiatry much more difficult. Psychiatric practice is not just the application of learned technique, no matter how exclusive or inspired it may claim to be. The practice presupposes a sort of human understanding by the psychiatrist. Human understanding is not merely the ability to explain human actions, attitudes, mental states, in terms of some theory which, as such, is necessarily general. All such theories remain somehow on the surface, for they are incapable of grasping precisely what it is that makes a person this one person, distinct from all others.

The spirit of the times—the *Zeitgeist*, if you will—is a useful concept if one refrains from endowing such a mythical entity with any kind of existence or reality. It is useful only because it expresses the fact that the most different phenomena of an age have something in common, reflect some trend in human life which exercises its influence on everyone's existence. The *Zeitgeist*, or the general cultural atmosphere in which a person grows up and lives, is as much a part of his environment as are the people who surround him or the conditions under which he works. Psychiatry is finding it rewarding to give consideration to these cultural—in the

widest sense, spiritual—conditions, as much as to the factors constituting the social situation of the individual. For the "world" of which the individual is himself a part, and which is at the same time set over and against him, is not the world describable by objective sociological analysis, but the world as he sees it, from his own individual standpoint. It is in many instances of primary importance for the psychiatrist to ascertain to what extent this standpoint is truly that of this one individual, and to what extent it is taken over, unexamined, from the environment and is perhaps inadequate to the needs of the person.

Reluctant though he may be, the psychiatrist in dealing with his patient cannot do much more than to seek some sort of compromise in all this. He must be wary of driving his patient towards an attitude of full realization, for this carries with it the danger of exposing him to the hostility of the group, and he must, on the other hand, help the patient towards a form of life in which he may again feel himself and his existence as meaningful. Ethics and esthetics, so important in the science of man, are therefore important to psychiatry also. Philosophers have often, in the course of history, voiced what the world in general did but darkly sense or did not know at all. But it cannot be predicted that the world will move according to the formulas of the philosophers. The power of well being, comfort, security and passivity is overwhelmingly great; it constitutes the modern siren song.

But what consequences and what directions may be drawn from all this for the future of psychiatry as a science? Though predictions are as uncertain as prescriptions are presumptuous, we must nevertheless attempt to map out some sort of program, or at least to delineate some sort of picture of what is going to happen in our field in the near future. Such an attempt is less risky the more conscious we are of the preliminary nature of all we may say and the more willing we are to modify our plans in the wake of new experience.

Of one point we may be certain: psychiatry will have to be more than ever a medical discipline. The recognition of the causal role of somatic factors, and of the therapeutic

effect of physio-chemical methods, underscores the need for a thorough knowledge of medicine as a prerequisite for doing responsible and successful psychiatric treatment. By the same token, the basic disciplines of psychiatry must be accepted by medicine. Anthropology, social and experimental psychology, the "normal" basic psychiatric science disciplines derive from faculties of philosophy and are not taught in medical schools. Even clinical psychology, an important aspect of psychiatric science, is rarely part of the young psychiatrist's training. As a result, the psychiatrist is handicapped at times when he attempts to think out new methods of approach to disease not already catalogued in his textbook, and the doctor who does not specialize in psychiatry is not adequately equipped to deal with the host of psychiatric problems he encounters in daily practice. The answer to this is as thorough teaching of the basic science disciplines of psychiatry as those of the purely medical sciences.

We may also be fairly certain of another point which, though already discernible, is more of a general vision than a clearly outlined program. We have come to realize that psychiatry, while undoubtedly and strictly a medical discipline, must at the same time be more than this. The psychiatrist in research and in practice is not justified in restricting his endeavors to one aspect of the human being. He has to take account of man as a whole and in the totality of his vital, social, cultural situation. Paradoxical though it may sound, the statement is nonetheless cogent, that to be truly a psychiatrist, one has to be more than a psychiatrist, more than a specialist. As we mentioned above, he must be a humanist. While scientific inquiry and methodology must always form the solid foundation of our discipline, upon this foundation may be erected the edifice of a psychiatry which will be the "applied science of man."

The ideal goal of the psychiatrist is to achieve wisdom, over and above the circumscribed knowledge that science, as it is understood today, affords. Psychiatry could do well with a philosophy of its own. Almost a century has passed since philosophy was formally expelled from psychiatry, but she returns inexorably to remind us that the old

problem of the relationship obtaining between mind and body still exists. Philosophy can claim no jurisdiction in matters pertaining to psychiatry and medicine proper. And it would be inappropriate to demand that the psychiatrist be a philosopher in the academic sense. But surely it is legitimate to demand from him an awareness of the fact that the problems in his purview transcend in their ultimate significance the field of purely empirical inquiry and that human existence extends beyond the strictly "natural" into the world of ideas, of truths, of values. The knowledge of man provided by dynamic psychiatry has made it clearer than ever that it is the inner life of the individual which is of paramount importance.

CONCLUSION

As I close this dissertation, I am aware that I have ranged far afield, with thoughts extending lightly in the clouds; yet all of me is planted solidly with my respected colleagues in the mental hospital, the scene of our labors. Earl Bond spoke feelingly of the necessity of giving the hospital psychiatrist a place in the scheme of things and he asked that all scientific day dreams be checked by the facts which the hospital psychiatrist has in his possession. I feel that my score in that test would not be high and yet it is necessary at times to soar from the hard facts of too many sick people, too little help, too little of everything furnished too late.

I know the futility of asking overworked and fatigued men to look up from their labors in order to see something grand in the overall scheme of things; yet look up we must and, when we do, we can better serve not only the progress of psychiatry, but also the progress of man to a fuller and better life.

If the science of man brings enlightenment to psychiatry, psychiatry can repay this debt amply by keeping in mind the great dignity of man and what human nature really is. The psychiatrist, even more than others, is entitled to make his own the words of the poet, Terence:

"Nil humani a me alienum puto."

(Nothing that concerns a man do I deem alien to me.)

FRANCIS J. BRACELAND, M. D., EIGHTY-THIRD PRESIDENT, 1956-1957: A BIOGRAPHICAL SKETCH

HOWARD P. ROME, M. D.¹

In a characteristic fashion, Frank Braceland's preface to the 129th Annual Report of the Psychiatrist-in-Chief of the Institute of Living recalled a eulogy given 100 years previously by his distinguished predecessor, a founding member and a president of this Association. Dr. John S. Butler had said of a fellow worker:

His equanimity and calmness checked the unduly excited; his suavity and quiet dignity calmed the turbulent; his kindness, cheerfulness and wit, with his ready repartee, cheered and amused the desponding, while his rare conversational powers and his fund of anecdote and of general and useful knowledge, made him the welcome companion of all.

As drawn by Dr. Butler the vignette was strikingly, although unintentionally, autobiographical. One hundred years later its author, the pioneer American psychiatrist, whose humane and enlightened care of the mentally ill, Charles Dickens commended as "a great moral lesson," was himself recalled in a similarly inadvertently autobiographical manner by the 83rd president of the Association. Frank Braceland's selection of this century-old tribute exemplifies Fichte's observation: ". . . the sort of a philosophy a man has depends on the sort of man he is."

Then too, the brash observations of youthful peers have a quality of insight which is often as penetrating as it is mordant. The editors of *Clinic*, the yearbook of the 1930 class of the Jefferson Medical College, recalled, among others of the attributes of the "Black Prince," "his resourceful sense of humor" and "his ability to make friends." They recognized with Carlyle that "true humor springs not more from the head than from the heart . . . its essence is love."

Braceland had entered Jefferson from LaSalle College in Philadelphia in 1926. Fifteen years later his alma mater was to give him a doctor of science degree, the first of 4 academic recognitions. The citation with which Canisius College in 1956 conferred

upon him the degree of doctor of humane letters echoed the tribute of his classmates, ". . . He is warm, generous, kindly, understanding with a delightful sense of humor and combines all the qualities which we would expect to find in a person who loves his fellow-man. . . ."

The best postulancy for a psychiatrist is the personal experience of sharing with others the vicissitudes of life. Frank Braceland's life is a mosaic of variegated experiences. His father, John J., had died when Frank was 4 years old leaving him and 3 younger children to be raised by their mother, Margaret L'Estrange Braceland, a persevering woman devoted to her family. Happily she lived to see the full maturation of her long years of effort. Frank's collegiate education was the richer because of its late start. He came to academe by a most unlikely route. He was a semiprofessional baseball player, a swimming instructor and an athletic supervisor in a youth center of Philadelphia's "Brewerytown." In his typically laconic fashion he says of this: "I learned the hard way to be multidisciplined." He was too, for there was also a short-lived, sudoriferous career in boxing which has since furnished an inexhaustible store of anecdotes in the wry genre of the neighborhood gymnasium.

His choice of psychiatry at the termination of a chief residency at the Jefferson Medical College Hospital must have been determined in part at least by those alchemical years. His facetious remarks about being multifaceted only thinly veil the versatility his close friends have long appreciated. Despite most tempting offers as a testament to his recognized potentialities in surgery, pediatrics, obstetrics and internal medicine, he was persuaded to seek training in psychiatry by the experience of being a physician-companion to a patient recovering from a profound depression.

For a third generation Philadelphian, Kirkbride's was a natural place to turn to.

¹ Section of Psychiatry, Mayo Clinic, Rochester, Minn.

Under the tutelage of Bond, Strecker, Smith, Appel and Palmer, Braceland matured professionally in the intimate preceptor-pupil atmosphere of the Pennsylvania Hospital. From 1932 to 1935, he was an assistant physician at 44th Street—the Department of Mental and Nervous Diseases, Doctor Kirkbride's hospital. In 1935, he went to Europe as a Rockefeller fellow in psychiatry.

At age 35, in the turbulent 1930's, the opportunity to travel and study abroad was a rare one; as Falstaff advised "... to be relished with the saltiness of time." Dr. Earl Bond had suggested Zurich and Burghölzli. Braceland was an assistant physician there until early 1936: lectures, ward services, the Hochschule and excursions. European study always has been partial to peripateticism and for the pavement-reared Philadelphian this characteristic led to a *wanderjahr* which ran a full continental gamut. How does one assay the value of this kind of experience? The constantly shifting partial pressures of influences, some clearly defined, others vague, still others wholly subliminal, mold the slow change which shapes a life. A walking trip in the Tyrol, a series of discussions with Thomas Mann, Jung's and Adler's lectures, a visit to the colony at Gheel, these and many other catalysts accelerated the fermenting decision to return to Philadelphia.

Braceland, while working as a clinical clerk for Kinnier Wilson, received a cabled invitation from Dr. Bond to return as clinical director of the department of nervous and mental diseases at Pennsylvania Hospital. This invitation crystallized a future. Thereafter Braceland entered into the unique heirarchy of the associate staff of the Institute of the Pennsylvania Hospital. In this setting he served as an apprentice and a journeyman. His private practice-teaching arrangement gave him faculty status as an assistant professor of psychiatry in the Graduate School of Medicine of the University of Pennsylvania and, from 1939 to 1941, as an associate professor at the Women's Medical College.

In late 1941 his teaching and administrative accomplishments led to his becoming dean of the medical school and professor of psychiatry at Loyola University, in Chicago. The advent of World War II precipitated

him into another sphere of administrative medical activities to which he was committed, in one or another capacity, until the termination of his active duty with the medical department of the Navy in 1946.

For his wartime service, the decoration of the Legion of Merit was presented to Braceland by the Secretary of the Navy, acting for the President of the United States. The citation that accompanied the decoration acknowledged Braceland's

Outstanding services . . . as Special Assistant to the Surgeon General . . . as Chief of the Division of Neuropsychiatry . . . for the procurement and training of medical officers and enlisted personnel. . . . His medical knowledge and ability contributed immeasurably to the welfare of the Navy Medical Corps during these critical years.

Since those years Frank Braceland's contributions to various departments of the federal government have been almost too numerous to list. As a member of the Special Medical Advisory Board to the Veterans Administration, he represented both psychiatry and neurology. He performs a similar service as a member of the Armed Services Medical Advisory Board. Since 1953, he has been a member of the Health Resources Advisory Committee of the Office of Defense Mobilization as well as of the National Advising Committee on Selection of Physicians, Dentists and Allied Specialties. Former President Hoover appointed him, in 1953, to membership on the Commission on the Reorganization of the Executive Branch of the Government. He is a consultant to the surgeons general of the Army and of the Navy of the United States and, since 1950, he has been a member of the Advisory Committee to the Department of Defense (Rusk Committee).

The multifacets that comprise the panoramic scope of Braceland's interests and activities seem to increase in number with the years. At the termination of 5 years of active duty in the United States Navy he was asked to establish a section of psychiatry at the Mayo Clinic. During the next 5 years he not only succeeded in doing this but also, as professor of psychiatry in the Graduate School, University of Minnesota (Mayo Foundation), he created a program for fellowship training in psychiatry.

The state of Minnesota expressed its gratitude in the certificate of appreciation its Governor Luther Youngdahl awarded for the herculean task Braceland performed as organizer and chairman of the Governor's Mental Health Advisory Committee. Through his patient and persistent efforts, an archaic program for disenfranchised patients of state mental hospitals was replaced by one which merited the national attention it received.

Frank Braceland has the singular talent of being able to recruit enthusiasm and interest. The facility with which he can invigorate others is matched only by the ease with which he orchestrates their efforts. Walter Lippmann has said, ". . . the final test of a leader is that he leaves behind him in other men the conviction and the will to carry on." The trail of continuing success that Braceland has left meets this test.

The admiration and respect which are commanded by the efficiency and fairness of the examinations of the American Board of Psychiatry and Neurology rest heavily upon Braceland's contributions. As its secretary-treasurer during the 6 years of its most lush growth, and as its president in 1952, he earned the appreciation of many anxious candidates by his kindly efficiency and scrupulous fairness. The advice he gave to candidates (and personally takes) recalls in *double entente* Longfellow's palliative:

Let nothing disturb thee,
Nothing affright thee;
All things are passing.

This is the attitude for which he personally strives. His writings reflect it. It was expressed most lucidly in the delightful reminiscence of 7 years of experience as an officer of the board. The title of the tribulation signified it: "Secretary of the Board: Apologia Pro Vita Sua." In his 1955 chairman's address to the Section on Nervous and Mental Diseases of the American Medical Association, he was careful to explain that his were lesser, purely collateral opinions, subtitled, "Obiter Dicta." The only fitting response to an *apologia* and an *obiter dictum* is the one made by an horatian friend: *multum demissus homo*; freely translated—a real modest guy!

His move to the Institute of Living at

Hartford, in 1951, recreated the atmosphere of John Butler's day; in the words Dickens used to describe Butler's supervision, Braceland's work has been "admirably conducted on enlightened principles of conciliation and kindness." In Connecticut, as in Minnesota, Washington, Illinois and Pennsylvania, he has been active in teaching and all public affairs relating to mental health: Chairman of the State Society Committee on Mental Health of the Connecticut State Medical Society, member of the Medical Advisory Committee of the Veterans Administration Hospital at Newington, member of the Board of Advisors to St. Joseph's College, consultant to Hartford Hospital and St. Francis Hospital, clinical professor of psychiatry at Yale University, living up to the Sophoclean admonition:

A man of worth

In his own household will appear upright
In the state also.

His worth in his own house is attested by his labors for this Association; his membership on the executive and nominating committees, on the coordinating committee on professional standards, on the Isaac Roy award and the Salmon committees—and now the presidency.

Three facets perhaps are more revealing than any of the foregoing: his devotion to his religious faith, to his family and friends and to his books. The award to him of the signal honor of knighthood in the Order of St. Gregory speaks eloquently of his faith and of the recognition of his aspiration by his church. Because he is devout, he is free from that "horrible air of rectitude" which scandalizes as it reminds one of Dylan Thomas' male-nurse so smugly conscious of the radiance of his own nimbus.

To his wife, Hope, and his young children, Faith and Michael, he is affectionately known as a do-it-yourself householder with 10 thumbs proving, as a good teacher should by *argumentum ad demonstrandum*, the innate perversity of inanimate objects. The members of his household see him as an incarnated Johnny Appleseed, whose humus-bedded brood of geraniums promises to dispossess them of their lovely summer home on the bay at Watch Hill. He is a beachcomber by avocation, devoted to fascinating the en-

tire family with his discoveries in the tracks of the ocean's feet along the sands. All the children who know him see his real forte as a prestidigitator able to snatch money out of thin air. With his friends he shares the secret quest for the accolade of the Breton peasant: a private symbolism signifying the uninterrupted opportunity to live and work simply on a commonplace level.

Frank Braceland has a bibliomaniac passion. On his numerous trips about the country his luggage largely is a small bookmobile. As the afflicted indulgently describe it, there is no satiety of the passion for books. With a Jason-like strategy, Braceland fortifies himself against the tasks he is called to perform with periodic browsing in favorite

bookstalls in out-of-the-way shops. His major hunger temporarily slaked, he can better sink his teeth into less palatable fare.

His book-piled study in his home, as well as his office in the Institute for Living, completes any picture of him. There, looking down on his desk from all four walls are his books and portraits of his friends.

The quotation from Sherrington with which he closed his presidential message in the December, 1956, JOURNAL expresses his personal credo in the elegant manner he so deeply admires, ". . . we have an inalienable prerogative of responsibility which we cannot devolve, no not as once was thought, even upon the stars. We can share it only with each other."

EFFECT ON BEHAVIOR IN HUMANS WITH THE ADMINISTRATION OF TARAXEIN¹

ROBERT G. HEATH, M.D.,² STEN MARTENS, M.D.,³ BYRON E. LEACH, Ph.D.,
MATTHEW COHEN, AND CHARLES ANGEL, Ph.D.⁴

In this report of work in progress, we describe the effect of the administration of a protein substance, which we have named taraxein,⁵ extracted from the serum of schizophrenic patients. Taraxein has been given on 17 occasions to nonpsychotic volunteers and on 1 occasion to a schizophrenic in remission. In all, 20 human subjects have been used in this study. All experiments were designed as double-blind control studies. A variety of nonspecific substances were employed as controls including the protein fraction extracted from serum of normals by the same procedure as that used to obtain taraxein from schizophrenic serum (5 occasions); another protein fraction, ceruloplasmin, obtained from normal serum (3 occasions); known inactive solutions of taraxein (2 occasions); normal saline (2 occasions); and a weak solution of sodium amytal (1 occasion). Nonspecific control injections were given on 13 occasions. Four of the subjects received nonspecific substances exclusively, 2 of the 4 receiving nonspecific substances on two occasions. Four subjects received active taraxein on one occasion and an inert substance on a second occasion; 1 individual received 2 inert sub-

stances plus 1 active substance; another subject, active taraxein on two occasions and an inert substance as a third injection; 2 subjects, active substance on two occasions. When more than 1 substance was given to 1 subject, the subsequent injections were always given on the same day (Table 1).

In our previous preliminary report on the clinical aspects of this work(1), we described the effect of the administration of taraxein to 2 human volunteers, 1 of whom also received 2 inert fractions as a control; and our first observations of the effect of taraxein with its administration on 30 occasions to 11 monkeys with chronically implanted cortical and subcortical electrodes. To date we have administered the taraxein on 53 occasions to 20 monkeys with the chronically implanted electrodes. Many dif-

¹ Presented at Divisional Meeting of The American Psychiatric Association, Montreal, Canada, November 9, 1956. Illustrated with 16 mm. sound motion picture films. Supported by grant-in-aid from The Commonwealth Fund.

² Authors are from the department of psychiatry and neurology, Tulane University School of Medicine, 1430 Tulane Ave., New Orleans 12, La.

³ Special Foreign Fellow, The Commonwealth Fund.

⁴ Authors wish to express appreciation to Warden Maurice H. Sigler, Louisiana State Penitentiary, Angola, Pa., for making arrangements to conduct the experiments with human volunteers; to all those inmates of the penitentiary who volunteered for the experiments; to N. F. Otilio and William H. Miller for technical assistance; and to Irene Dempsey for help in correlating data and for secretarial assistance.

⁵ Taraxein from the Greek *taraxis* meaning confusion, or disorder of the mind.

ferent fractions have been tested in monkeys to control the study. Although we now possess considerably more information than at the time of our preliminary report, there is much information which we would like to possess but have not yet been able to gather. In this progress report we present the additional data on our clinical studies, being fully aware that much remains to be learned, but hoping that others will become interested in broadening the studies.

Factors leading up to the isolation of this blood fraction were briefly reviewed in the presentation at the APA meeting in Chicago, 1956(1). For several years we had obtained subcortical and cortical recordings from a group of schizophrenic patients(2, 3) which revealed a characteristic spike and slow wave pattern in the septal region and rostral hippocampus (Fig. 1B). Accumulated evidence indicated that the introduction of physiological variables to this region produced profound changes in blood chemistry. This led to the exploration of the comparative effects of schizophrenic and normal serum on the speed of adrenaline oxidation. Our findings suggested that adrenaline was more rapidly oxidized by the serum of schizo-

phrenics who were free of systemic disease than in normal control subjects(4). Similarly, we(5) found in confirmation of Altschule's work(6) that levels of reduced glutathione were lower in a statistically significant number of schizophrenics without systemic disease than in normal control subjects. Both indicators, *i.e.* the speed of adrenaline oxidation and the low glutathione levels, were, however, nonspecific since non-psychotic persons with various systemic diseases showed similar alterations. It was known from work of others(7, 8) that copper levels were increased in chronic disease processes and in schizophrenia, and that in diseases other than schizophrenia, the elevated copper levels were due to increased levels of the copper globulin oxidase, ceruloplasmin. In investigating the adrenaline oxidation phenomenon, we noted that the addition of copper speeded the process considerably. In one study we isolated ceruloplasmin from serum and found that this was the substance in serum responsible for the increased oxidation. Details of this study including the isolation of one inhibitor of the process (albumin) are given in a separate article(9). Recent evidence suggests the

FIG. 1A — Scalp and subcortical recordings in a nonpsychotic human subject (intractable pain).

FIG. 1B.—Cortical and subcortical recordings in a schizophrenic patient.

presence of additional inhibitors. Inasmuch as patients with schizophrenia showed the increased speed of oxidation of adrenaline and lowered levels of reduced glutathione in the absence of systemic diseases, we postulated that perhaps a copper protein accounting for these differences might be qualitatively different if this chemical phenomenon, namely increased levels of oxidizing enzymes, was an important factor in psychotic behavior. To test this hypothesis we isolated ceruloplasmin from the serum of normals and schizophrenics and administered it to monkeys with chronically implanted electrodes. With the intravenous administration of ceruloplasmin from schizophrenic patients, the monkeys occasionally showed mild behavioral changes characterized by reduction in level of awareness resembling incipient catatonic symptoms. This did not occur with the administration of the substance extracted from normals. It was noted during the extraction procedure, however, that at one point in the process—namely when the euglobulins were precipitated out by lowering the pH to 6.2—a blue color was present in the precipitate from schizophrenic serum but not in the precipitate from normal serum.

Since we had these mild behavioral changes with administration of schizophrenic ceruloplasmin, we postulated that perhaps this apparently different precipitate might be significant. Therefore, instead of discarding it, as is routinely done in the extraction of ceruloplasmin, we set up a procedure for processing this substance. When the end-product of this procedure was administered to the monkeys, most profound behavioral changes resulted; the behavior resembling very closely that seen in schizophrenic patients. The monkeys appeared dazed and out of contact. They were catatonic and the extremities could be readily molded into various positions. In association with this, there were clear-cut alterations in the electrical recordings (Fig. 2), particularly from the septal region. Since we had accumulated considerable data on recordings from human schizophrenics which showed essentially the same characteristics, we reasoned that if our recordings in schizophrenics were significant, then administration of this substance should induce schizophrenic-like behavior in the humans (we could not reasonably call the monkeys' behavior schizophrenic since this diagnosis is

FIG. 2.—Subcortical and cortical recordings in monkey before and after administration of taraxein.

dependent upon the reporting of the patient). In this regard, our previous data on electrical recordings from humans were of extreme importance since we would otherwise have had no logical reasons for assuming that the behavioral reactions we observed in monkeys were anything more than simple toxic effects which many compounds are capable of producing. Other compounds which altered behavior in monkeys have never produced this

characteristic type of recording. Thus, by means of the electrical recording, we are apparently able to make meaningful cross-interpretations of behavior from animals to man.

MATERIAL AND METHODS

Schizophrenic patients, from whom blood was drawn for the experiments described, were selected from 4 local psychiatric hospi-

tals. Two were large hospitals for chronic care and 2 were acute treatment centers. All donors were physically well but showed clear-cut schizophrenic symptoms. They were not receiving physical treatment or drug therapy at the time, the drugs having been discontinued at least 3 days before blood was drawn. Diets in the 4 hospitals varied considerably. The patient group varied considerably in age and duration of hospitalization.

In all experiments thus far, the taraxein has been extracted from serum pooled from several patients. This has been necessary since the amount of taraxein needed to create a reaction in the host requires a minimum of 400 ml. of serum, or approximately 900 ml. of blood. For some experiments the pooled serum from the various classical subcategories (catatonic, hebephrenic, paranoid and undifferentiated) were pooled and processed separately. When serum was pooled according to diagnostic subcategories of schizophrenia, the donors were reexamined to check diagnosis. In most instances, 250 ml. of blood were drawn from each patient, using the standard Cutter Laboratory blood drawing sets. The serum was immediately separated from the blood cells, cooled and then transported to the medical school laboratories for processing. The fractionation process usually required 5 days.

In this experiment, the method employed to extract taraxein is a modification of the Holmberg and Laurel technique for isolating ceruloplasmin(10). The procedure which follows is for the processing of 400 ml. of schizophrenic serum (for control studies, similar quantities of serum from normal subjects are used).

1. Approximately 1,000 ml. blood obtained from schizophrenic patients is allowed to clot (2 to 3 hours) and is then centrifuged at 2,500 RPM for 20 minutes at 10° C. Usually 250 ml. from each of 4 patients is pooled.

2. Serum is separated from the clot by suction and is then cooled to 4° C. and divided into four 100 ml. portions.

3. To 1 volume of serum, 1.2 volumes of saturated ammonium sulfate (4° C.) is added while stirring. This mixture is then centrifuged for 3 hours at 4° C. at 2,700 RPM.

4. The supernatant is decanted and discarded. If the residue is not packed well, only as much supernatant is poured off as is possible without losing appreciable quantities of the residue.

5. The residue from each of the 100 ml. portions is then dissolved in 100 ml. of cold tap water (10° C.) and these solutions are then pooled and transferred to 1½" dialysis tubing for dialysis for 40 hours against cold tap water (10° to 15° C.). Our tap water varies in pH between 9.8 and 10.2.

6. The dialyzed material, which usually has a volume equal to about twice the original serum volume, is removed from dialysis and is allowed to stand at room temperature until it warms to 16° C. The pH at this stage is usually between 9.3 and 10.2.

7. The pH is adjusted to 6.6 with 0.4% acetic acid. The acetic acid is added dropwise from a burette with constant stirring. The pH adjustment at this stage normally requires 8 to 12 ml. of 0.4% acetic acid per 100 ml. of serum originally used (32 to 48 ml. for the 400 ml. batch).

8. The suspension with pH adjusted to 6.6 is centrifuged at 2,700 RPM for 20 minutes at 18° C.

9. The residue is solidly packed and glossy and is usually green to greenish-yellow. (The supernatant is poured off and retained to be further processed for ceruloplasmin.)

10. The 6.6 precipitate is suspended in a small volume of cold (10° C.) tap water by thorough mixing with a glass rod. Then sufficient cold tap water (10° C.) is added to make the volume equal to one-half the original serum volume, i.e. 200 ml.

11. This suspension is then transferred to 1½" dialysis tubing and dialyzed 10 to 11 hours against cold tap water (10° to 15° C.). This dialysis causes very little change in volume.

12. After removal from dialysis the material is allowed to stand at room temperature until it reaches 16° C. At this point the pH is usually between 8.0 and 10.0. Distilled water equal to the volume of the dialysate is then added.

13. The pH is then adjusted to 6.8 by the dropwise addition of 0.4% acetic acid while stirring continuously with a glass rod. The pH adjustment at this point usually requires between 0.5 ml. and 1.0 ml. of the 0.4% acetic acid for each original 100 ml. of serum, or 2 ml. to 4 ml. for the 400 ml. batch.

14. The volume is measured at this point and is approximately the original serum volume, i.e. 400 ml. The suspension is then cooled to between 3° C. and 1° C. in an ice bath.

15. An equal volume of chloroform-alcohol mixture (one part chloroform to 9 parts of 90% ethanol) which has been pre-cooled to between -12° to -25° C. is then added to the chilled suspension with continuous stirring. The temperature of the mixture at this point goes up immediately to between 5° and 11° C.

16. The mixture is then allowed to stand at room temperature for 3 hours.

17. This is centrifuged at 2,700 RPM for 30 minutes at 18° C.

18. The supernatant fluid is discarded and if a layer of chloroform collects below the solid residue, it is also discarded.

19. The residue is then mixed with 0.86% sodium chloride solution using 25 ml. for each 100 ml.

of serum originally used or 100 ml. for the batch. This mixture is dialyzed for 18 hours against running tap water.

20. The dialysate is then dialyzed for 15 hours at 4° C. against 1,200 ml. of 0.86% sodium chloride solution (300 ml. for each 100 ml. of original serum) the pH of which is 9.0.

21. This material is then centrifuged for 15 minutes at 4° C. and 3,000 RPM.

22. The volume of supernatant is then measured and 1.85 volumes of cold saturated (4° C.) ammonium sulfate is added and mixed.

23. The material is then centrifuged for 1 hour at 4° C. and 2,500 RPM.

24. The supernatant fluid is discarded and the residue is drained as completely as possible.

25. The inside walls of the centrifuge bottles are wiped with tissue to remove excess ammonium sulfate solution.

26. The residue is suspended in saline (0.86%) using 1 ml. for each 400 ml. of serum originally used. This suspension is transferred to a dialysis tube ($\frac{3}{4}$ ") and the centrifuge bottle is then rinsed twice using an additional $\frac{1}{2}$ ml. of saline each time, and this also is added to the dialysis tube.

27. The material is then dialyzed 40 hours against cold running tap water.

28. After removal dialysis the material is centrifuged 15 minutes at 2,500 RPM at 18° C.

29. The supernatant solution which usually has a volume of 2 to 3 ml. for each 400 ml. of serum may be retained at 4° C. for several hours (4 or 5) and still have activity or it may be quick-frozen in a thin walled container using liquid nitrogen. In the event that it is necessary to quick-freeze with dry ice and alcohol, the material should be in a sealed container so that it is not exposed to carbon dioxide.

This method has been slowly improved since we were first able to extract taraxein from the serum of schizophrenic patients. We expect to be able to improve the method further as we gain further understanding of the characteristics of taraxein. Through modifying the procedure over the course of the last year, we have become aware of a number of factors that will inactivate the substance. Currently, other techniques of extraction are being investigated. A detailed report of these findings will be forthcoming in another publication as we learn more of the identification of this fraction.

At present, even when all known factors considered in the outline of method are closely controlled, we do not always obtain consistent activity in the taraxein fraction. We do not have a method for accurately quantitating the amount of taraxein in our preparations. Our only method for determining the presence or absence of activity is

with animal assay (1). It has been our practice to administer intravenously to the monkeys the amount of substance we are able to obtain from 400 ml. of schizophrenic serum. If marked behavioral and EEG changes occur in the Rhesus monkeys, we consider the preparation to have maximal activity. If the taraxein from this amount of schizophrenic serum produces no observable behavioral or EEG changes in the animals, we consider the preparation inactive even though the test actually indicates that we have not reached threshold dose for this animal. The taraxein given to the human subjects in this experiment was rapidly administered intravenously. The actual amount of fluid administered was 1 to 3 ml. This was the quantity derived from 400 ml. of serum.

The experiments with human subjects are divided into 5 groups. Each of the 5 was designed to answer one or more specific questions. Although they have provided us with considerable information, several important questions remain unanswered. Further experiments are planned to gain needed additional information.

In obtaining volunteers, groups of prisoners in the cell blocks were first called together and the nature of the proposed experiments described. Those interested were then asked to sign a release form which detailed all known information concerning the project, released Tulane University and State authorities from responsibility, and clearly stated that no reward could be provided for this service. The first step in screening was to eliminate all persons with a history even vaguely resembling a psychotic state in themselves or any member of the family. Potential subjects were then taken to the prison hospital where a careful screening interview was conducted with each candidate by at least 2 psychiatrists. A minimum of a seventh grade education was required. All of the prisoner volunteers fell into the diagnostic category of psychopathic personality since they displayed extractional behavioral trends to varying degrees. In each subject, evaluation of the motivation for the anti-social act for which they were imprisoned was a primary consideration. A careful appraisal of underlying dynamic character traits was attempted with the consideration that it might

be of some value in predicting the type of reaction they might show after the administration of the taraxein. There are 3 nonprisoner subjects in the series, all of whom received taraxein. One is a laboratory technician in our department and well known to us. The second manifested a low average intellectual level but no evidence of psychotic symptoms. The third was a known paranoid schizophrenic. He had been under treatment for some time and was in a state of remission in that his secondary symptoms of overt persecutory delusions and referential ideas with auditory hallucinations had subsided. Detailed reports of mental status examinations and histories on all subjects are available, but too lengthy to be included here.

The experimental design for each group and the questions to be answered by each were as follows (Table 1):

Group I.—This experiment, which included 2 subjects, was designed to answer the major question as to whether or not administration of the blood substance from schizophrenics which produced characteristic behavioral and subcorticogram changes in monkeys would result in schizophrenic-like behavior in humans. In contrast to the monkeys, the humans could report their thoughts and feelings, thus providing the data necessary to compare these reactions with behavioral changes seen in schizophrenic patients. Each of the subjects received 1 injection of active taraxein from pooled schizophrenic serum and 1 of the subjects first received 2 injections of an inert substance as a control.

Group II.—This experiment included 5 subjects and was designed to provide a larger and more thorough study with more controls. Each subject was examined by 4 psychiatrists. Psychological testing was conducted before, during, and at conclusion of the reaction. Very active substance was given to 2 subjects; normal saline to the third; the protein fraction obtained by the same procedure from normal serum was administered to the fourth subject; the fifth volunteer received a weak taraxein injection. The subject receiving the fraction from normals was later given a weak solution of taraxein. The weaker solutions provided information regarding dosage levels. In this experiment;

pooled serum subdivided according to the conventional subcategories of schizophrenia was employed.

Group III.—This was a heterogeneous group and included the 3 nonprisoner volunteers. Our motivation in administering taraxein to a schizophrenic in remission was to determine if there would be a difference in reaction from that seen in nonpsychotic subjects. Our reasoning was that we might obtain some leads as to possible underlying mechanisms in the phenomenon. Inclusion of the 2 additional subjects served to determine if residency in a state prison was prerequisite for the reaction.

Group IV.—This group included 6 subjects. Four were given taraxein. In addition, 6 injections of control substances were made, 3 of which consisted of the protein extracted by the taraxein isolation method from serum of normals and 3 were of the ceruloplasmin fraction from normal serum. As is apparent, some of the subjects received 2 injections, either 1 of taraxein and 1 of the substance similarly extracted from normal serum or 2 injections of different normal fractions (1 subject). In this experiment we selected as volunteers only first offenders who had minimal prison sentences in an attempt to obtain a prisoner group with the least degree of psychopathy. Also in this experiment, pooled serum subdivided according to the conventional diagnostic subcategories of schizophrenia was employed. Our purpose in doing this was to determine if the taraxein extracted from serum of patients with one particular subcategory of schizophrenia would, when injected, induce similar symptoms in the recipient.

Group V.—Two of the 4 subjects of this group received 2 injections at least $3\frac{1}{2}$ hours apart; a third subject, 3 injections each separated by at least $3\frac{1}{2}$ hours; a fourth subject received only 1 injection—a total of 8 injections: 5 of active taraxein; 1, the fraction extracted from normal serum; 1 of normal saline; 1, a weak solution of sodium amylal. All injections contained the same volume of fluid and were purposely made to be of exactly the same color. This experiment was designed to determine whether or not the same individual would react differently upon receiving taraxein of one sub-

category of schizophrenia than he would when receiving taraxein of another subcategory.

On all experiments, moving picture films were taken before and at various periods following the administration of the compounds.

RESULTS

All patients receiving taraxein developed symptoms which have been described for schizophrenia. This does not imply that each time we have processed taraxein, especially in the earlier stages, we obtained an active product. It has been our policy always to test at least 1 dose of each preparation on monkeys prior to setting up a study with human volunteers. The details of information we have gathered concerning the factors in processing which might inactivate this substance will be given in our paper on identification. With the exception of a few early occasions, we have always processed blood from normals along with that of the schizophrenics, usually isolating the ceruloplasmin as well as the fraction that comes out by the extraction method for taraxein. In monkeys we have given the fraction extracted from normal serum by the taraxein isolation method on 10 occasions to 7 monkeys without producing behavioral or EEG changes. In the 5 human subjects to whom this fraction obtained from normal serum was administered as a control, we induced no reaction. Likewise, in the 3 normal subjects we received ceruloplasmin extracted from normal serum, there was no reaction. There is, however, one questionable situation in regard to the administration of the protein fraction from normals which is detailed below under Complications. In none of the other control experiments which included 2 doses of known inactivated taraxein and, on 3 occasions the administration of saline, or Sodium Amytal, has there been any behavioral change.

Some rather consistent basic alterations in behavior have occurred in every subject receiving taraxein. This is in contrast to rather marked variability in secondary symptoms which have appeared. Basic alterations are similar to those described by Bleuler (11) as "fundamental symptoms." Secondary symptoms resemble Bleuler's "accessory symp-

toms." The onset of symptoms is gradual beginning in every instance between 2 and 10 minutes following the injection. Symptoms increased slowly in intensity reaching a peak between 15 minutes and 40 minutes, after which they begin to subside. The longest duration of clinically detectable symptomatology in the nonpsychotic population has been 2 hours. No residual abnormalities have ever been observed beyond this period except in the case of the 1 schizophrenic patient.

GENERAL REACTIONS

The characteristic general change is evidence of impairment of the central integrative process resulting in a variety of symptoms. There is marked blocking with disorganization and fragmentation of thought. There is impairment of concentration. Each subject has described this in his own words—some saying merely "I can't think"; "my thoughts break off"; others, "I have a thought but I lose it before I can tell you anything about it," etc. "My mind is a blank" is another common expression. It becomes impossible to express a complete thought. Often they will state only a part of a sentence. They appear generally dazed and out of contact with a rather blank look in their eyes. They become autistic, displaying a lessening of animation in facial expression. Subjective complaints of depersonalization are frequent. Attention span is markedly shortened with increase in reaction time. The symptoms often produce apprehension in the patients. The commonest verbalization of their concern is "I never felt like this in my life before." Virtually all have made this statement. Memory was impaired only during states of profound stupor. Recall was excellent in all cases except for what transpired during periods of deep stupor. Sensorium has always been clear when subjects are capable of reporting.

SPECIFIC REACTIONS

The test subjects have developed secondary symptoms of various types and degrees. In an effort to gain some knowledge as to whether or not the subcategories of schizophrenia represented different diseases, we

have carried out a variety of studies with the various test groups.

In the first test group of 2 subjects, 1 batch of taraxein was extracted from pooled serum of schizophrenics of various subtypes. Each subject received one-half the material and the secondary symptoms in one were predominantly catatonic whereas in the other they were predominantly paranoid.

In 3 of the test groups, II, IV, and V, taraxein was extracted from schizophrenic serum which was pooled in accordance with the classical subcategories, *i.e.* paranoid, catatonic, hebephrenic, and undifferentiated. There has been no consistent correlation between the presenting symptoms of the donors and those of the recipients with regard to secondary symptoms. On one or more occasions, symptoms characteristic of all the schizophrenic subcategories have been induced. Thirteen subjects in these 3 test groups received taraxein extracted from serum pooled according to subcategories. On 4 occasions, the recipient presented predominantly the symptomatology of the donor group, whereas on 9 occasions, predominant symptoms of the recipient fitted into schizophrenic subcategories other than those presented by the donor group.

After our experience with the first 2 prisoner volunteers, we were interested in determining if, on the basis of mental status examination, we could accurately predict the type of secondary symptoms that would be induced by the administration of taraxein. As indicated in our preliminary presentation, our predictions were not accurate. In Groups II, IV, and V, all examiners independently listed their predictions prior to the administration of the substance. Although there was almost universal agreement among the examiners, the reactions in the subjects were not at all in accordance with the predictions—in fact, the predictions were wrong in the majority of cases. It must be pointed out, however, that the predictions of the examiners were based on only one interview. It is possible that longer observation may have resulted in more accurate predictions, but this does not seem likely since the character traits in the group were quite distinct.

On 2 occasions (Group V), a single subject was given 2 test doses of taraxein ex-

tracted from patients with different types of schizophrenia. In 1 instance a subject first received taraxein from paranoid patients and developed some paranoid symptoms; namely, referential ideas, suspicion and auditory hallucinations. Later, after all effects had cleared, he was given taraxein from patients with undifferentiated schizophrenia which induced predominantly catatonic symptoms. The other subject, receiving 2 injections, first received taraxein from undifferentiated schizophrenics and developed a mild undifferentiated schizophrenic reaction with predominantly primary symptoms. His second injection of taraxein, after all symptoms had cleared, was from catatonic patients. This induced full-blown catatonic symptoms. It may be an important observation that the symptoms were much more intense in both individuals following the second injection.

In test Group IV in which all subjects were first offenders and whose history of antisocial behavior was shorter, the reactions were the same. Two subjects in Group V were also first offenders. Reactions were in no way different from those induced in more chronic offenders. In the 2 nonschizophrenic volunteers of test Group III, the induced reactions were again essentially the same. These observations indicate that the effect of taraxein on inducing schizophrenic symptoms is not related to intensity of psychopathic behavior nor to residency in state prisons.

The response in the 1 schizophrenic patient in remission who received taraxein was quite different from that seen in the non-psychotic volunteers. We know of no way to evaluate accurately intensity of reaction once full-blown secondary symptoms appear, but the symptoms induced were quite marked and were characterized by more profound depersonalization than those seen in the non-psychotic volunteer group. The principal differing characteristic, however, was the duration of reaction. The full-blown open psychotic symptoms induced persisted to a gradually diminishing extent for 4 days, in contrast with the maximum duration of 2 hours in the nonpsychotic volunteers.

Psychological tests given some of our taraxein subjects by H. E. King have shown clearly a defect in performance roughly ap-

proximating the dosage administered and the observed clinical effects.

COMPLICATIONS

In these clinical studies we have had two noteworthy complications. On 3 of the 18 occasions when taraxein was administered to humans, the subjects developed nausea and 1 subject vomited. These effects persisted for less than 5 minutes following the injection and prior to the onset of the psychotic symptoms. All occurred in the earlier experiments. We believe that they were caused by insufficient destruction of nonspecific proteins at one stage of the processing. With a minor modification of the processing, they have been eliminated.

Another serious complication occurred when one subject, receiving a fraction labelled as coming from serum of normals, developed a full-blown psychotic reaction. Though it appears that this was a case of mislabelling, we believe it necessary to report it along with all evidence surrounding the incident. The tubes were labelled by the chemists at 6:00 a.m. after they had worked on the procedure throughout the previous night without sleep. This fraction was processed along with several batches of schizophrenic serum. One batch of schizophrenic serum consisted of 2 doses of undifferentiated schizophrenic serum. One dose of the fraction labelled undifferentiated was active and produced psychotic symptoms in a human subject. When we administered the second dose labelled "undifferentiated" (other half of the total amount) to the same subject who developed a full-blown reaction from the fraction labelled "normal," it produced absolutely no response. We thought that if one dose consisting of one-half of the match of undifferentiated taraxein was active, then this second dose consisting of the other half of the same batch should have been also. On the basis of these factors, we strongly suspect that one dose of normal and one dose of undifferentiated schizophrenic fraction were mislabelled. In addition to this, we have administered the fraction extracted from normals to 5 other human subjects and 10 monkeys with no effect whatsoever. Despite this evidence, however, we recognize that because of this com-

plication we must test many more normal fractions before being absolutely certain that the effects cannot be induced by administration of the fraction from normals.

DISCUSSION

It is obvious that although we have accumulated considerable data there are still many unanswered questions. At this stage we feel it would be unwise to attempt to draw any sweeping conclusions or to enter into lengthy theoretical speculation. Our data tentatively suggest that schizophrenia, despite the nature of presenting symptomatology, may be one common disease entity. Several other factors seem apparent. One is that different test subjects have different thresholds for the appearance of psychotic symptoms with the administration of this substance. This is based on the observation that similar amounts from the same batch produce varying intensity of symptoms in different subjects. Also, duration of effects following the reaction vary considerably suggesting a different speed of breakdown of the substance. Although cognizant of the danger of speculating on the basis of one case, the results in our one schizophrenic subject suggest that in schizophrenic persons, the ability to detoxify this substance or a product formed by the interaction of this substance with some constituent of the human organism is impaired.

We have gained the impression, although it is difficult to substantiate, that the nature of the presenting symptoms is a function of dosage rather than of the recipient's character traits or the disease symptoms presented by the donor. So-called primary or fundamental symptoms have appeared with lower dosages whereas hebephrenic and catatonic symptoms predominate with high dosages. Supporting evidence for this speculation is the observation that a more intense color is usually noted in the precipitated fraction from catatonic and hebephrenic donors. Of course this observation is highly speculative since we as yet do not have a method for accurately quantitating the amount of taraxein present. Several questions have been raised concerning the similarities between reactions in subjects receiving this substance and those in volunteers receiving

the psychomimetic drugs, D-lysergic acid and mescaline. The principal difference is that subjects in this study have presented the characteristic picture of schizophrenia whereas those receiving the conventional psychomimetic drugs had only some schizophrenic symptoms and the most prevalent were typical of toxic psychosis (visual disturbances, disturbances of perception and sensorium, etc.). Our subjects have never shown symptoms of autonomic nervous system stimulation so characteristic of D-lysergic acid reactions.

We considered the possibility that an immune reaction might develop from taraxein which perhaps would render the subject insensitive to later injections. We therefore repeated the experiment after an interval of 11 weeks in one subject. Response to the second injection was virtually the same as to the first.

In our preliminary paper we reported that we had extracted taraxein from the blood of so-called pseudoneurotic or ambulatory schizophrenics. These were patients in our outpatient department who presented some fundamental or primary schizophrenic symptoms without secondary or accessory symptoms. We noted, however, that in order to produce a reaction in monkeys, taraxein from a larger amount of serum was required. As yet we have been unable to explore this area further, but hope to report on it in the near future.

SUMMARY

Work in progress centered about the isolation of taraxein from the serum of schizophrenic patients and its administration to

monkeys and human volunteers is presented. The taraxein was extracted from a variety of schizophrenic patients in 4 institutions and administered on 17 occasions to nonpsychotic human volunteers and on one occasion to a schizophrenic patient in remission. Several additional studies are planned or in progress and we expect that in the near future it will be possible to present considerably more information.

THE EFFECT OF CULTURE CHANGE ON THE NEGRO RACE IN VIRGINIA, AS INDICATED BY A STUDY OF STATE HOSPITAL ADMISSIONS¹

DAVID C. WILSON, M.D., AND EDNA M. LANTZ²

Norman Cameron in his textbook *Behavior Pathology* describes desocialization as one of the abnormal reactions found among the mentally sick. He designates two causes, namely isolation, a voluntary action, and segregation, a separation from the group by group action(1). Since the Negro in Virginia had been segregated for years, it was decided to compare the mental hospital statistics for the white and the Negro in Virginia to see if there was any evidence in the state hospital population to substantiate Cameron's statement regarding the effect of segregation.

Virginia was a convenient state for such a comparison, because the Central state hospital, Petersburg, had admitted all the Negro patients committed in the state, and the other 3 state hospitals had admitted all white patients committed, regardless of overcrowding that might exist. This policy regarding admissions has been pursued for at least 50 years. Also the department of mental hygiene and hospitals of the State of Virginia, under the direction of Dr. Joseph Barrett, had established an admirable statistical department under the direction of Edna Lantz. The very efficient cooperation of Miss Lantz, a co-author of this paper, made the study possible.

The first study is shown in Table 1. Here the number of patients in the state hospitals is shown and compared to the white and Negro population. The rate per 100,000 shows 2 outstanding features; first, that the Negro ratio has always been greater than the white and second, that while the white ratio increased by 113 points, the Negro ratio increased by 343.6. The ratio per 100,000

Negro population has more than doubled in the 40 years.

There are so many reasons why patients stay in hospitals, that it was thought best to study admissions only. Therefore Table 2 was made to show a summary of first admissions and re-admissions of mentally diseased, mentally defective and epileptics in Virginia by race and rate per 100,000 population, 1914 to June 30, 1954.

This study of admissions gave us very similar results to those seen in Table 1. The white ratio had increased slightly, by approximately 20 points. The white rate of admissions had reached a peak in 1939 and had since been dropping. The rate for

1946-55.....	1,455	2,581,555	48.2	773	737,125	104.8

Negroes, however, had increased by 63.2 points and there was no similar peak.

It was decided then to study only first admissions. Table 3 shows the total first admissions to state hospitals by race, the population of each race in the state and ratio per 100,000 of white and Negro population.

Table 3 shows that the findings emphasized by the other tables are still present in the study of first admissions only. This study shows that the white population of Virginia has increased by nearly a million since 1918, while the Negro population has increased by only 46,000. This is especially remarkable since the Negro birth rate is higher than that of the white. The rate per 100,000 white during the last 10 years has decreased and now approximates the rate of 1918-25. The Negro rate of admissions per 100,000 Negro population is still increasing and is now more than double the white and 41 points higher than during the period 1918-25.

The argument has been advanced that mental illness among the Negroes was due in the main to feeble-mindedness, alcoholism and epilepsy. In order to study this question the first admissions to the state hospitals were studied when all admissions because of feeble-mindedness, alcoholism and epilepsy without psychosis were excluded. This study is presented in Table 4.

This study shows the same picture: namely the greater number of Negroes ad-

mitted per 100,000 population and the great increase of mentally ill Negroes admitted during the last 10 years over the earlier years, when the ratio to population is considered. There is also this marked drop in the ratio of white admissions during the last 10 years.

This study ruled out mental deficiency, alcoholism and epilepsy as the cause of the difference between white and Negro and between Negro in 1918 and Negro in 1954.

This difference in admission rate is shown more accurately by Table 5 which gives the percentage of the total population, white and Negro, as well as the percentage of admissions, white and Negro.

This study shows the decline in admissions proportionately of the white, the relative decrease in the Negro population, but the continued increase in the Negro admissions.

Since mental deficiency, alcoholism and epilepsy did not explain the difference noted in the first study, another division of first admissions was made under separate categories according to diagnosis. This was done to see if any one mental disease syndrome could be held accountable for the differences noted.

Table 6 shows the result of this study. In this table the rate per 100,000 of the population of the race under consideration is given in each one of the categories con-

sidered. These figures are given for the census years, since the figures can be checked more accurately by the population figures. This is done for all the years except 1955, which is estimated.

This study shows that for the white race, patients with cerebro-arteriosclerosis or senile psychosis, there has been an increase in rate. The rate for schizophrenia increased and then diminished slightly while the diagnosis of manic-depressive psychosis has been made much less frequently. There has been no increase in the number of patients with syphilis, but an increase in the number admitted because of alcoholism. The Negroes have a higher rate as well as increase in the senile-arteriosclerotic group, as well as those diagnosed as schizophrenia. The group diagnosed manic-depressive is larger, while those admitted because of alcoholism is smaller than the white. Those admitted because of syphilitic infection are more numerous than the white and more in 1955 than in 1920, but the difference is not sufficient to answer the problem. The table shows quite definitely that the reason for a larger ratio per 100,000 of Negro patients admitted now than 30 years ago, and also a higher rate of Negro admissions than white, is that the rate of senile-arteriosclerotics and especially of

the patients admitted because of schizophrenia is higher. The rate per 100,000 of schizophrenics for the white changed from 6.4 in 1920 to 7.2 in 1955, while the rate for Negro admissions, which was 12.0 in 1920, changed to 21.7 in 1955. The greater number of admissions of Negroes in the senile-arteriosclerotic and the schizophrenic groups than whites, as well as the striking increase in the rate per 100,000 for Negroes in the 2 diagnostic categories, indicates that it is Negroes suffering from these 3 conditions that makes the difference in the number of admissions found to exist for the two races throughout the years and in the number of Negroes admitted in 1920 as contrasted with those in 1955.

The admissions in the senile arteriosclerotic group for both races increased during each decade, but the rate for the Negro was always greater. The Negro, because of his economic status, would be more inclined to transfer the care of the older members of the race to the State. As we wish to know whether segregation of the Negro was a factor in causing the difference in the hospitalization of the two races, it was thought proper to compare the tendency of both races to hospitalize patients over 65. This comparison is shown in Table 7.

TABLE 7

FIRST ADMISSIONS OF PATIENTS OF 65 AND OVER COMPARED BY NUMBER, RATE PER 100,000 OF POPULATION OVER 65 FOR EACH RACE, AND THE PERCENTAGE OF THE TOTAL ADMISSIONS

1955*.....	474	241.9	32.6	155	327.2	18.9

* Estimated

The outstanding findings in this table are that while more Negroes over 65 are being admitted in 1955 than in 1920 and the rate per 100,000 of Negro population over 65 has gone up, the percentage of total admissions is not as great as the white. In other words, more white people are admitted who are over 65 and it is not the presence of old people that explains the preponderance of senile and cerebro-arteriosclerotic mental disease among the Negroes. One startling find was the great increase of the white population of Virginia over 65 during the last 10 years and the fact that there has been no such increase in the number of Negroes over 65. The Negroes die younger.

In conclusion then, the stress and strain of life and not just the aging process produces the senile and arteriosclerotic psychoses among the Negroes. The segregation of the Negro can be considered as one of the stresses of the Negro's life.

There were 2 other findings in our initial study that seemed worth further investigation. The first was the apparent decrease in white admissions to state hospitals in Virginia. Is it possible that this finding was due to a decrease in mental disease among the white that was not shared by the Negro? The second finding was the very slight increase in the Negro population in Virginia since 1914, in spite of a relatively high birth rate. If this could be explained by the migration of the Negro to the North, would it be the mentally healthy Negro who migrated and left those more disturbed at home, thus accounting for the situation found in Virginia?

In order to answer the first question it was thought best to attempt to get a cross section study of the number of Virginians hospitalized for mental disease during 1954. In Virginia there are 3 private hospitals, 1 state supported private hospital, and 2 psychiatric wards in general hospitals connected with the 2 medical schools. There are 2 V.A. hospitals that take mental patients. These institutions do not account for all the hospitalized Virginians since many are in V.A. hospitals outside the state and a few enter private institutions in other states, such as Maryland, North Carolina and Connecticut. An effort

was made to canvass most of these institutions. Table 8 shows the results of this study.

The figures for the V.A. hospitals were taken from a survey of the V.A. hospitals. The figures for institutions outside of the State were based on letters from 10 private institutions answering to questionnaires. The figures from the Tucker Sanatorium are not official, but are certainly a very close estimate of the admissions to this hospital. It must be remembered that many of the patients admitted to the private hospitals have minor mental illnesses. They are not committable, therefore their numbers cannot be compared to the figures for the Negroes who are practically all sick enough to call for commitment.

The study indicates that the decline in state hospital admissions for the white race is due to the increase in the use of other facilities for the care of the mentally ill. The rate per 100,000 population for the Negro race is still higher, but about what is to be expected from the study of previous years. Before 1940 the private institutions and the psychiatric wards did not exert such an influence as they have since.

The migration to the North and Northwest started to have an effect on the Negro popu-

* Estimated

lation of the South soon after 1914. Table 9 indicates the condition of those Negroes who lived in the North, as far as mental disease is concerned. The rate for New England could be given only for 1922. The rate for New York is compared with that of Alabama and Louisiana.

The admissions of Negroes to state hospitals in northern states are certainly higher per 100,000 than in the South. Malzberg, in 1940, reported an incidence of schizophrenia (based on hospitalized cases and standardized for age) of 16.9 per 100,000 for native white persons of native parentage, 26.4 for native white persons of foreign parentage, and 32.8 for foreign born persons, and 51.1 for Negroes (2). We can conclude, therefore, that the incidence of mental disease among the Negroes of Virginia is certainly not increased because the more stable members of the race have migrated to the North. Indeed it would appear that the more stable ones stayed at home.

SUMMARY

1. A study of white and Negro patients hospitalized for mental illness in the State of Virginia shows a higher ratio for Negro patients when the rate per 100,000 population of respective races is considered. Also there is a tremendous increase of Negro admissions now as compared to 1914.

2. This same finding is reflected in a study of first admissions of the mentally ill.

3. This difference is not due to mental deficiency, alcoholism or epilepsy without psychosis.

4. The difference is due in the main to the number of Negroes admitted for senile psychosis, arteriosclerotic dementia, or schizophrenia. This figure is larger than that for similar white admissions and greater now than in 1918.

5. The number of Negroes admitted because of senile and arteriosclerotic diseases is not due to the admission of more older Negroes than white, because persons 65 and over make up a greater percentage of white admissions than of Negro. Also the increase in admissions of Negro patients 65 and over has not sufficiently increased over the years to explain the difference between admissions now and 40 years ago.

6. The rate of first admissions to mental hospitals per 100,000 of Negro population in Virginia, while higher than the white, is lower than the rate in northern states. This would indicate that the migration of Negroes to the North did not increase the rate per 100,000 of those Negroes who stayed in Virginia. The probabilities are that the more unstable members of the race migrated.

7. The apparent decrease of rate in the admission of white patients to the state hospitals during the last 10 years is due to other facilities for treatment, such as the private hospitals and the psychiatric wards in general hospitals.

DISCUSSION

The history of the United States over the last hundred years is one of change. The industrial revolution, the origin of great cities and the rise of both capitalism and organized labor have been only a few of the many rapid changes that have affected American life. However, the most rapid change, and perhaps the most extensive during the last 50 years, has been found in the South. The culture has been changed from predominantly rural and based on agriculture to urban and industrial (3). This period of change has involved all the people living in the area and has put pressures on each individual that always accompany change. Mar-

garet Mead in *The Introduction to Cultural Patterns and Technical Change*, states

While it is still not possible to say that a given culture is less conducive to mental health than another, because of our lack of cross-culture criteria for mental disorders, it is possible to say that under situations of stress and strain, of rapid change and consequent disorientation, there is likely to be an increase in manifest mental ill health(4).

In the South, therefore, during the last 50 years, there has been a steady migration from farm to city and from agriculture to industry. This change began soon after the Civil War, but has become accelerated especially in Virginia during the last 20 years. This change, with many others has altered the way of living in the South and undoubtedly has had a great deal to do with the manifest mental illness found in that area. Within the same area, however, the most profound has been the colored segment of the population.

Before 1865 the Negro culture as a whole was a slave culture. From 1865 to 1877 the Negro was given equal rights as a citizen by the 14th and 15th amendments to the Constitution. From 1877 to 1915 the Negro was segregated under the definite concept that he was an inferior being, lived in a culture of his own, and was supposed to know his place, which though respected, was nevertheless subservient to the white. The Negro was supposed to be very happy, very religious and free from the usual anxieties that troubled the white.

For approximately 50 years the Negro-white status was nearly stationary. White and Negro intermingled but with the relation of master to servant(5).

During World War I several things happened to change this condition. The Negro was well received abroad and found that there were places in the world where white and black lived together. There was the beginning of the industrialization of the South and the great movement from the farm to the city. The migration of the Negro to the North and Northwest began in earnest and has continued to the present day. Next came the depression and the Roosevelt administration, which brought the first legal successes of the Negro; then World War II when the Negro fought shoulder to shoulder with white, and finally the post-war period. Now

the Negro has won repeated legal battles, has become a political power to be reckoned with, and has wealth and power enough to be influential in the business world. There is now a substantial Negro middle class, and the wages paid the Negro are higher than ever before. The Negro no longer works on the small farm or as a domestic but has a position in the city or in industry.

Where the Negro of 1915 was poor, illiterate and a servant, now he is better dressed, owns his home and probably a car. He can go to high school, to college or university. He makes and spends more money, yet the last 40 years have been an uneasy time. There has been no definite place he could call his own. He is constantly stirred up by his needs, as well as by the propaganda of his leaders, by the Communists and by those politicians who would use his power. The labor unions came into the South and organized both white and black labor. The F.E.C.P. and the minimum wage law were enacted.

The Negro has improved economically since 1940. He has moved from an agricultural to an urban culture, as has the white man. He has been industrialized. He migrated to the North to better his condition. In spite of all this, he is more segregated now than 40 years ago and while then his status was fixed, now he has no status as he moves from a culture of his own into a white culture(6).

Forty years ago the Negro and white family lived across the street from each other. The children played together and the adult Negroes worked in the home or on the farm. The Negro had a definite status and in that position he was supposed to be happy while he sang his songs and prepared for the next world.

The relationship between white and colored was that of master and servant. The Negro had a place which was honorable and respected but definitely inferior. The white children of today do not know the Negro. The Negro servant has gone from the home and the Negro child is very closely segregated. The Negro of today is an unknown person, certainly until he reaches college or graduate school.

Cultural changes which are forced on a

people against their will, by fiat or by authority from outside or above have been found by the experts of the U. N. to produce major disturbances of mental health. Margaret Mead in her book recommends that such changes be brought about by understanding and cooperation at all levels of the culture. The total person and the total culture must be considered and the change must be made slowly with due consideration for the psychological make-up of the individuals. She points out that frustration of a subculture has the same effect as frustration of the individual.⁷ There will be regression and a return to more primitive forms of living. Richard L. Jenkins in his book *Breaking Patterns of Defeat* describes the average American Negro community as poor and under-privileged. It is characterized by more primitive, uninhibited living. The causes are undoubtedly cultural; the results are aggressive crimes and psychosis.

A social or a culture situation which gives rise to insoluble problems and much frustration may be expected to result in a higher incidence of schizophrenia than a social or culture situation which gives rise to less frustration(8).

Dr. Jenkins compares the Negro with the Jew as far as their ability to stand segregation is concerned. The Negro has a very loosely constructed family organization, and worships strength. The Jew has a very closely knit family and can admit weakness. The former culture under stress yields psychoses and aggressive crimes, while the latter develops psychoneuroses and the ability to stand suffering without retaliating.

The annual report of the department of welfare and institutions on commitments to county, city jails and city jail farms in the State of Virginia for the year ended June 30, 1955 gives us the following table.

TABLE 10
JAIL COMMITMENTS FOR THE YEAR ENDING
JUNE 30, 1955.

	White		Negro	
	No.	No. per 100,000 white population	No.	No. per 100,000 Negro population
	66,011	2,382	44,380	5,587
For drunkenness.	28,524	1,029	13,129	1,652

This table shows that the Negro community exhibits the other characteristic of a frustrated community, namely crimes of aggression.

The Negro in Virginia is far better off economically and legally than ever before but he is more closely segregated. He has lost the security of his own culture and is moving rapidly toward a middle class white culture. This period of uncertainty and close segregation parallels the increase in the rate of Negroes admitted to the state hospitals of Virginia for cerebro-arteriosclerosis, senile dementia, and especially for schizophrenia. Very few, if any, of the steps recommended by sociologists and cultural anthropologists, who are experts in culture change, have been carried out to protect the Negro or the white man as this change in relationship is brought about. It seems to us most reasonable to believe that the preponderance of mental disease in the Negro over the white man and its increase in ratio to Negro population in Virginia is due to segregation and to the period of uncertainty accompanying culture change.

CONCLUSION

A study of state hospital statistics for the State of Virginia from the year 1914 to the year 1955 shows the following:

1. There has been a larger ratio of Negroes admitted to state hospitals per 100,000 population of Negroes than of white per 100,000 white population throughout the 40 years.
2. There has been a tremendous increase in the admission rate for Negroes per 100,000 Negro population over the 40 years and the present rate practically doubles that of 1914.
3. This increase in rate is due mainly to an increase in senile psychoses, cerebro-arteriosclerosis and schizophrenia. Admissions for schizophrenia parallel in their behavior most closely the increase in the ratio.
4. The Negro has experienced similar changes to those of the white during this period with 2 additional factors: segregation has become more severe; and he is no longer the servant but the equal of the white.
5. It is felt that the fact that there is more mental illness among the Negroes of Virginia than among the whites and more mental ill-

ness among the Negroes in 1954 than in 1914 is due in large degree to segregation and to the uncertainties of the Negro race as they cross from one culture to another.

PSYCHIATRIC MANAGEMENT OF SUICIDE PROBLEMS IN MILITARY SERVICE¹

WILLIAM OFFENKRANTZ, M.D., EDWIN CHURCH, M.D., AND ROBERT ELLIOTT, M.D.^{2, 3}

This study was designed to determine the characteristics of individuals who threaten or attempt suicide and are brought to the attention of the military psychiatrist; and to test a method of management intended to prevent further suicide attempts.

METHODS AND MATERIALS

Individual Characteristics of the Population.—The subjects for this study were cases from an outpatient neuropsychiatry ("Mental Hygiene") clinic at the U. S. Army Hospital, Fort Devens, Massachusetts, during the months immediately following cease-fire in Korea. The observations cover the period August 1953 to December 1954. Many different types of units comprised the base, including a large prison stockade and 29 General Reserve Units in training. Among the latter, distribution by service function was as follows: 2 signal corps, 9 quartermaster, 6 medical, 8 ordnance, and 1 finance. Also stationed there was the major portion of a regimental combat team and a large school of the Army Security Agency. Some of the pertinent characteristics of peacetime military life at Fort Devens, as elsewhere, were discipline with or without harassment, enforced closeness, boredom, real and imagined inequities in assignment, and extra-military personal problems.

The 75 patients chosen were soldiers or civilian dependents. During the 15 months of the study, 54 threatened and 21 attempted

suicide and were brought to the attention of one of the 3 psychiatrists at the Army Hospital. A comparison⁴ group was established by selection of every tenth chart from the files of the Mental Hygiene Clinic during the same period. In this group were 2 cases from the suicidal series, which may represent the incidence of the problem of suicide in the Clinic's case load.

The general characteristics of the suicidal group were compared with those of the random sample to determine whether the two could be distinguished. Data were gathered describing age, circumstances of referral, referral source, military rank, race, mode of entry into service, diagnosis,⁵ religion, marital status, length of service, education, follow-up for continuation of life and military career, and the distribution of the cases among the Clinic's 3 doctors (approximately one-third being seen by each).

Method of Management.—The method of management was evolved from the following: (1) clinical interviews which gave no evidence of depression or psychotic confusion in an age group in which depressions are infrequent; (2) an impression that these soldiers and civilian dependents frequently gave historical evidence of crudely manipulative or delinquent behavior without evidence of symptomatic depression or psychosis; and (3) a hypothesis that the suicidal threat or attempt was an extension of this behavior: a method of emotional blackmail, moving people about the patient in ways that would make him more comfortable. This hypothesis was based in part upon the psychiatrists' reactions during the interviews with these patients.

⁴ This was called a "comparison" rather than a "control" group because the latter should have had a different kind of management for the same suicidal threats and attempts.

⁵ With regard to criteria for diagnosis, we adhered to the U. S. Army's Standard Diagnostic Nomenclature, which is similar to that of The American Psychiatric Association.

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² Authors' addresses are, respectively, School of Medicine, Univ. of Southern Calif., Los Angeles, Calif.; 299 Holt Drive, Pearl River, N. Y.; 8100 E. Jefferson, Detroit, Mich.

³ Grateful acknowledgement is made to David Rosenberg, Ph.D. (psychologist), and John R. Whittier, M.D. (director, Creedmoor Institute), for their assistance in the preparation of the manuscript; and to Mandel E. Cohen, M.D. (neuropsychiatric consultant).

The technique of management was as follows:

1. A personal interview was held with each patient by one or more of the 3 psychiatrists.
2. The psychiatrist who saw the patient discussed the information in the history, whether it had initially been elicited by that doctor or not, in an effort to establish rapport by making clear that the psychiatrist's interest extended to the point of informing himself about who the patient was and how he came to be there.
3. During this procedure the doctor arrived at a diagnosis, and an understanding of the nature and extent of the problem, based upon the history, the mental status, and (infrequently) the use of psychological testing.
4. Each patient was then told, by the use of the information that had been obtained, that the doctor understood his unhappiness.
5. He was told that he could not be helped in terms of his concrete demands: for hospitalization, for discharge, for change of assignment, for transfer, for change of physical profile, for light-duty slip, etc.
6. He was told that it was unfortunate, but true, that if he really needed to kill himself, the psychiatrist did not feel that anyone could stop him, and that therefore no one but the patient could keep himself alive.
7. He was told that if he killed himself it would be considered the act of a sane man on the basis of the interview, and his family would therefore lose any material benefits resulting from his death. He was also told that if he subsequently tried to kill himself and did not succeed, the army regulations provided that he would have to stand court martial for the offense.⁶
8. Whenever possible the referring physician, commanding officer, or other referral source was informed of these steps and encouraged to manage the patient in the same way, with the responsibility for such management resting upon the psychiatrist.
9. None of the patients was hospitalized and none was given a return appointment.⁷

⁶ The setting of these limits without a hostile context, hence without provoking retaliation on the part of the patient, was the crucial performance on the part of the psychiatrist.

⁷ The same procedure (steps 1 through 9) was

RESULTS⁸

The suicidal group was significantly younger than the comparison group (Table 1-A). The majority were in the 20 to 25 age range. Their mean age was 22.0 years; that of the comparison group 24.6 years. Fisch(1) reports the average age in his study as 23; Arieff, McCulloch and Rotman(2) as 20 to 30; and Schmidt, O'Neal and Robins(3) report the average age of the men in their study as 44; the women as 34.

The population was predominantly Caucasian (Table 1-B). There was no significant difference between the comparison and suicidal group with regard to marital status (Table 1-C); and none in religious preference (Table 1-D).

No significant difference appeared in the length of education (Table 1-E). Figures for the educational level attained within the suicidal group showed that 72% had more than 8 grades of education. This agreed with the experience of Arieff, McCulloch and Rotman(2) who found that in a series of 500 cases of attempted suicide, 76% had gone beyond the eighth grade.

There was no significant difference in the mode of entry into service between the two groups (Table 2-A). However, 3 attempts in a group of 17 draftees (1 to 5.7) when compared with 13 attempts in a group of 46 enlistees (1 to 2.5), is perhaps at least of borderline significance.

Table 2-B compares the length of service of the two groups. As might be expected, because of a positive correlation between months of service and chronological age, the suicidal group as a whole had less time in the army (Table 1-A). This difference was especially noticeable after 72 months of service. This is in accord with one of the original

followed with the civilian dependents with appropriate variations.

⁸ It was felt that suicidal patients resembled other neuropsychiatric patients more closely than they resembled soldiers in general. It follows, then, that the significant differences between suicidal and non-suicidal individuals do not stand out in this study as clearly as they might otherwise, because we selected a comparison group of other neuropsychiatric patients. Consequently we emphasize whatever differences appear in the tables by liberal use of the word "significant."

premises concerning the age range of the suicidal group in military service.

Comparison of military rank for both groups (Table 2-C) indicates an overwhelming predominance of privates with a negligible number of commissioned officers. These data agree with those of Fisch(1) who found only 4 commissioned officers in his series. The majority of his cases were in the bottom two enlisted ranks. Again this is probably at least partially a function of age.

Table 2-D indicates that the greatest frequency of referrals in both groups was from medical doctors in the unit dispensaries. This is probably a function of the way sick call was used by this group of soldiers to complain about army life in general, rather than

Totals	75	75		

of a particular physical illness. It was also, to some extent, a reflection of the referral procedure at the particular army base which required that almost every patient be seen by a doctor before coming to the Mental Hygiene Clinic. In addition, as the majority of

threats were revealed after coming to the Clinic (Table 3-A), it is clear that the large number of patients referred by physicians does not necessarily indicate that they were the first persons to whom the threat was revealed. However, the person indicated was always the first to know about the threat and to be in a position of responsibility for the soldier's welfare. Table 2-D seems to indicate a significant difference between the number in the two groups who were referred from confinement personnel.

Analysis of the attempts (Table 3-B) indicates slashing of wrists by far the most frequently chosen means. It might be expected that some attempts would involve the use of firearms, but it was extremely difficult for soldiers in garrison to gain access to loaded weapons except on the rifle range. Several authors comment on the relation between the method chosen for suicide and the seriousness of the attempt. Fisch(1) studied 114 suicidal attempts among which there was one death. He notes cutting of the wrists and ingestion of drugs or poisons as the most common methods. On the other hand, among 46 deaths by suicide among naval personnel during the same period,

TABLE 3

A. MILITARY PERSONNEL TO WHOM SUICIDE THREAT FIRST REVEALED

	Male	Female

Unknown	2	1
Totals	16	5

shooting and gas inhalation were the two most common methods employed. Hendin (4) reports that in his series inhalation of illuminating gas and hanging were the most common methods used in successful attempts. He found that cutting and ingestion of sleeping pills were more common in unsuccessful attempts. Stengel (5) reports that 25% of his series ingested drugs, with wounding and coal gas inhalation as next most common. Arief, *et al.* (2) assert that the method chosen serves as a fairly reliable index to the genuineness of the desire to die. Oliven (11) makes a similar statement.

Comparison of the diagnosis (Table 2-E) indicates a significantly larger number of "character disorders" and "immaturity reactions" among the suicidal group. Among the comparison group there was a larger number of "neurological problems," as well as "no psychiatric disease." These findings are in agreement with those of some workers and in conflict with those of others. For example, Teicher (6) in a study of 30 suicidal attempts among naval personnel reports that 24 were "insecure, inadequate, immature personalities." Fisch (1), in studying 114 attempts among naval and marine corps personnel, reports 43 "immaturity reactions," 23 "personality disorders," and 32 "psychotic reactions." Laufer and Casriel (7) reported on suicidal gestures among occupation personnel on Okinawa and found "most" of their cases to be "immaturity reactions." Raines and Thompson (8) however, in discussing 164 gestures and attempts found only 15 "character disorders" and 62 "schizophrenics," with 22 others classed only as "delirium."

Table 4 presents results of a follow-up study for continuation of life and outcome of service from 5 to 19 months after the patients were first seen. The most recent data were collected in July 1955. One patient in the suicidal group had died by suicide.⁹ For the rest, the table indicates a sig-

⁹ We have no other explanation for this death save a lack of diagnostic acumen. Within 12 hours after being seen at the Clinic, the patient went home on pass to his family's farm in New Hampshire. There he killed himself by driving a car behind the barn and running a vacuum cleaner hose from the exhaust pipe into the car. Obviously this was not an accidental death.

TABLE 4

FOLLOW-UP AFTER 5 TO 19 MONTHS
(MAY OR JULY 1955)

Soldiers	Comparison	Suicidal
Dead	0	1 (Suicide)
Alive	63	62

Totals	8	12

nificantly higher number of administrative discharges, *i.e.* undesirable, bad conduct, and dishonorable, among the suicidal group.¹⁰

DISCUSSION

The Data.—In a general way it may be seen that by contrast with the comparison group the suicidal group were younger, in service a shorter time, referred from confinement status less frequently, and were more frequently diagnosed as "character disorders" and "immaturity reactions." On follow-up they were more likely to have received an other-than-honorable discharge.

The two groups showed no significant differences regarding race (both predominantly Caucasian), incidence of divorce, mode of entry into service, religious preference, years of education, rank (both groups were chiefly privates), and sources of referral (chiefly M.D.'s in both groups).

¹⁰ Significance as used in this study does not connote "statistical significance" except with regard to there being a smaller number referred from confinement, and fewer honorable and more administrative discharges in the suicidal group, in which case the results do meet the test of statistical significance ($p = < .05$).

Relation to Civilian Population.—The study indicates the characteristics and results of such management in only a particular youthful age group. The problems leading to their suicidal threats or attempts are probably not the same as those in the fifth and sixth decades of life; consequently we would not recommend a similar method of management for these age groups. This point of view is supported by others. Hendin(4) found that the age of those with intermediate or maximal intent to die was 5 years higher than the average of the entire group. He also notes that the mean age at which suicide occurs is 10 years above that of the unsuccessful attempts. Schmidt, *et al.*(3) similarly classified 120 suicidal attempts as "serious" or "not serious." The average age in the "serious" group was 48; in the "not serious," 34.

No generalizations are warranted from this study to a civilian population. It is quite likely that because of the nature of military life, more people are brought to the attention of psychiatrists on an army post than would be in civilian life. In our opinion this is because in the peacetime army with which we worked, a principal goal of life was the avoidance of criticism. Consequently, responsible people were particularly vulnerable if they were to "disregard" the suicidal problem by not referring the patient immediately to a psychiatrist.

The Clinical Interview.—In clinical interviews, these patients gave no evidence of symptomatic depression or psychotic confusion, but rather of impulsiveness, recklessness, and a particular kind of exploitation, *i.e.* to make someone else more interested in taking care of them than they were in caring for themselves. Only 2 gave evidence of psychoneurotic symptoms. They did not speak of feeling guilty, hopeless, or unworthy. They showed no hypochondriacal preoccupation nor somatic delusions. There was no evidence of anorexia, insomnia nor psychomotor retardation. They gave no evidence of a desire to die or be killed; but rather that they did not "care" or at worst felt "as if they might as well be dead." At cross-sectional mental examination, some were tearful and agitated, raising the possibility that they may have been

cases of previously retarded depression who were beginning to move about more freely, with attendant increased risk of suicide. However, after obtaining the history, in no case did we find a diagnosis of depression of a psychotic or psychoneurotic nature warranted (Table 2-E).

These patients showed histories characterized by delinquency, truancy, and poor school record in general, temper tantrums, enuresis, syncopal attacks, inability to postpone gratification, poor work record, and a family history frequently described by the patient as without harmony. This is comparable to the observations reported by Teicher(6).

Emotional Blackmail.—Although we believed that what we were dealing with were essentially threats and gestures, rather than serious attempts to die, we could not ignore that each gesture carried with it the possibility of success. Batchelor(9) stresses the point that the psychopath, because he is so prone to act impulsively, may kill himself before there is time for anyone to intervene. Studies in which the seriousness of unsuccessful attempts is assessed(1, 6) generally include psychopaths in the not serious or minimal intent groups. In our nomenclature these would be the "antisocial" or "asocial character disorders."

We were impressed by the extent of personal uneasiness experienced by the commanding officers, non-commissioned officers, and medical doctors in the face of this behavior. Clearly someone had to assume responsibility for managing the patient: to take steps by enforced hospitalization to prevent him from killing himself or to take the chance that he would not do so. The feeling that "something must be done" is a well-established reflex among members of the medical profession in response to a patient's complaint, and the pressure upon the physician to "do something" when the patient presents suicide as the "chief complaint" is particularly great. (See the discussion on these points by Stengel(5).)

This urge to "do something" stems in part from the traditional concept that patients at the onset of an acute psychosis may use this as a means of asking for help by letting someone know of their extreme distress. We felt that in patients with character disorders,

the same qualitative situation exists; i.e. they are letting someone know of their distress, the "appeal character" of the attempt according to Stengel(5). This differentiation of character disorder from psychosis must be made on other grounds as described above.

Management.—The rationale for management arose from the following considerations:

1. Certain individuals are incapable of setting internal limits upon doing as they wish (an idea not original with us). Further, they probe the environment to find how far they can go in getting their wishes granted. It is necessary, therefore, for the environment to set limits for them, and it should be made clear that the limiting agent is firm but not antagonistic. The absence of antagonism is essential and therapeutic. First, it makes clear to the patient that the psychiatrist, representing the environment, has not been frightened by his behavior, and hence is not subject to intimidation or manipulation. Second, it allows the patient little opportunity to feel that he must overcome disbelief or anger by resorting to a more serious attempt.

2. Hospitalization must be avoided because it enables the patient to escape from the pressures of the specific situation which precipitated his action. Also, whenever a patient has been hospitalized, it whets his appetite to try again. Further, it was felt that in some patients their guilt about being hospitalized would require them to seek re-hospitalization as reassurance that they had been sick in the first place.

Nor are the benefits of hospitalization lost to the other men in the unit. Lowered morale and an epidemic of similar behavior among the other troops may result. Fisch(1) reports that all his patients were hospitalized as a result of their attempts. We feel that his material demonstrates one of the unfortunate consequences of such hospitalization in that he was unable to rehabilitate any who expressed an unwillingness to return to service.

3. These patients were experiencing despair as a reaction to the anxiety engendered by enforced closeness, discipline, boredom, and inequities of assignment (real or imagined); rather than as the result of guilty fear or helpless anger. Consequently, sui-

cide becomes either a lever to move the world into a more comfortable arrangement, or an act of revenge upon the army which is experienced as not having loved and cared for him properly. [See Thompson(10).]

Therapeutic Aspects.—In addition to preventing the patient from making himself more sick in the dependency-fostering setting of the hospital, this method of setting external limits constitutes a positive psychotherapeutic performance. These patients are not available for psychotherapy in the ordinary sense, because they clearly do not desire to change their patterns of behavior. Thus two goals were achieved despite the calculated risk. First, the patient, like a child, can be helped to grow by learning what is expected of him; i.e. he is given the opportunity to become responsible for his own behavior. Second, he is not permitted to blackmail others into changing unpleasant circumstances for him by threatening or attempting suicide. That is, his efforts to strike back at the parental figures who have thwarted his dependency gratification are forced into other channels. The purpose was therefore, to enlarge his range of adaptive response by allowing him to accept that this particular response was a failure.

As an incidental finding for the "others," particularly the commanding officers and medical doctors, this procedure had an educational value. It suggested to them that psychiatry has no magic. It further demonstrated the difference between taking a threat seriously and allowing oneself to be blackmailed. Finally, it reminded other physicians of the difference between individuals with depression and those with character disorders, in that the latter tend to use suicide for the purpose we have discussed.

Weaknesses of the Study.—There were three major defects in the study. First, cases seen prior to the formalization of the management were included. Second, a uniform group of exact criteria for the diagnoses were not used, nor were specific criteria provided for inclusion or exclusion regarding a particular diagnosis. Third, it was always known, either before the clinical interview or during it, that the patient had either threatened or attempted suicide. This raises the possibility that diagnoses might not have

been made at all on a number of these patients save for the psychiatrists' awareness of the suicidal problem.

Regarding the first defect, about half way through the study, the three psychiatrists agreed that what each had been doing until then seemed familiar to all and that for the rest of the study each would be saying approximately the same things to his patients. The question remains unanswered as to what the patients heard the doctors say, or for that matter, whether the things agreed upon really were said.

Regarding the second defect, the U. S. Army Standard Diagnostic Nomenclature was used and this represents a defect inherent in present-day psychiatric methodology to which we fell heir.

SUMMARY

This study describes a group of outpatients who had threatened or attempted suicide and were brought to the attention of military psychiatrists.

Data are presented comparing the characteristics of this group with a similar number of nonsuicidal patients chosen at random from the files of the same mental hygiene clinic.

The data indicate that the suicidal group were younger, had less time in service, and were more frequently diagnosed as "character disorders" and "immaturity reactions" than the comparison group. Within the suicidal group itself, the frequency of attempts was higher among enlistees (1 per 3.5) than among draftees (1 per 5.7).

Each patient was handled in a like manner, and none was hospitalized nor seen a second time.

A follow-up of 5 to 19 months indicated a low incidence of suicides among the pa-

tients managed in this way (1 in 75); also a significantly higher number of administrative discharges, and a significantly lower number of honorable discharges among the suicidal group.

Comparison with civilian population, characteristics of the clinical interviews, rationale of management, therapeutic aspects, weaknesses of the study, and the nature of emotional blackmail are discussed.

CONCLUSIONS

1. Suicide problems in service, because of the special characteristics of military life in interaction with specific problems of the patients, are significantly different from those in civilian life. Some of these characteristics and problems are amenable to study and are described.

2. The low incidence of actual suicide on follow-up suggests that the method of man-

OBSERVED DIFFERENCES BETWEEN SUICIDAL and COMPARISON GROUPS

FIG. 3

agement described was successful. However, a comparative study on a similar group, using a different method of management, would be required to validate this point.

DISCUSSION

COL. ALBERT J. GLASS (Washington, D. C.).—From my experience the authors of this paper are correct in stating that suicidal gestures or attempts by military personnel create marked uneasiness in those who occupy positions of command or medical responsibility. It is probable that the restrictions of military existence produce a greater frequency of acts and threats of self-destruction in the young military population than a comparable age group in civilian life, although I know of no statistical data that will prove or disprove this assumption. At any rate, suicidal gestures are a common cause of referral to the military psychiatrist. Under these circumstances the psychiatrist is eagerly accepted as the proper person to solve the dilemma of whether to react against the intuitively understood hostile behavior of the suicidal subject with equal aggressiveness, or to yield to the threats of suicide by removing the individual from the situation either by hospitalization, reassignment, or some other environmental manipulation. Faced with this responsibility the military psychiatrist also suffers from anxiety since he has no certain method of identifying the few whose suicidal at-

tempts are an ominous portent of later more successful self-destructive efforts from the many whose suicidal gestures may be safely disregarded. Too often the military psychiatrist finds it more comfortable to allay his own anxiety and hospitalize all such referrals. As indicated in this paper, hospitalization unfavorably influences the morale of the group and facilitates the suicide subject to fixate neurotic and immature patterns of adjustment.

The unique value of this presentation lies in its account of a direct and operational approach to this problem. Methods in the management set forth herein can be duplicated by others. The experience of the authors indicates that impressive results are obtained by a firm but sympathetic management which is based upon (1) clarification of the situational conflict; (2) placing of the responsibility for the self upon the subject; and (3) the blocking of secondary gain.

It is perhaps not surprising that this technique is similar to methods employed in the treatment of combat psychiatric casualties. Since World War II, military psychiatrists who work with psychological problems that are engendered primarily by external stress conditions appear to arrive independently at similar conclusions; namely, (1) that abnormal behavior or symptoms are best understood in terms of adaptation to the present, rather than psychopathology caused by conflicts of the past; (2) that individuals must be aided to overcome and master anger and anxiety due to realistic external conditions and social obligations; (3) medical evacuation and hospitalization only confirm and continue helpless and evasive patterns of behavior.

Undoubtedly there are risks in any method which insists upon further efforts by the individual to continue functioning in what is for him a distressing and painful existence. Some failures are inevitable as demonstrated by repeated suicidal attempts, or due to errors in diagnosis such as the one death reported in this paper. However, even the most elaborate and time-consuming techniques of observation and diagnosis are not infallible.

The authors correctly point out that their technique is not directly applicable to similar phenomena in a civilian setting or in an older age group or in a mental hospital population, all of which are much less homogeneous in age and psychopathology than the subjects of this study.

I congratulate these authors for a splendid contribution in an area of military psychiatry in which there has been much uncertainty and doubt. Their work demonstrates that practical research can be carried out in the "field" by making use of the clinical material available. Because an operational and duplicable approach was employed, information obtained by this experience can be repeated and, if confirmed, will add to our knowledge and therapeutic armamentarium.

THE ROLE OF THE PSYCHIATRIST IN TEACHING COMPREHENSIVE MEDICAL CARE¹

DONALD C. GREAVES, M. D.²

Comprehensive medical care has been defined as a science which includes not only the treatment and cure of sick human beings, but the prevention of disease and the preservation of health. It is essentially an effort to humanize medicine, and to train the physician as a comprehensive human biologist with emphasis shifted from the training of more physicians to the training of better ones. The physician so trained should begin his professional life with the facts and technical skills necessary to make diagnoses and institute treatment, as well as the ability to recognize the importance of social, cultural, and emotional factors on genesis, prognosis, and therapy of disease. Such training is the acknowledged goal of comprehensive medical care.

In the last decade, medical educators have been increasingly concerned as to whether their students were adequately prepared for the practice of this kind of medicine. Such concern did not spring unprovoked from faculty meetings, but, like most of the advances in medical sciences, resulted directly from the unfulfilled needs of patients. There was a growing awareness of the importance of emotional factors in clinical medicine. The practicing physician, they were told, finds that a large number of his patients have illnesses which are either primarily emotional or strongly influenced by emotional and social factors. In their own teaching centers they saw that treatment frequently suffered from the increasing complexity of modern scientific medicine. They saw treatment become broken into a large number of specialty clinics with much duplication and waste. They saw contact broken between the patient and his student physician. There was little opportunity or time for the physicians or students to get to know patients as human

beings with human problems. At the same time, they knew that unsatisfactory patient care was most frequently the result of an inadequate teaching program rather than vice versa. Thus, there was a movement toward re-evaluation and reorganization of curricula. For example, a sweeping reorganization of the fourth year curriculum was instituted on a full scale at the University of Oklahoma School of Medicine and University Hospitals as early as July 1952(1, 2). The Oklahoma program demonstrated the value of this method ("The Longitudinal Curriculum"), and it has since been adopted at several medical schools.

After a year's preliminary study, the New York Hospital-Cornell Medical Center established the "Comprehensive Care and Training Program" for senior medical students beginning with the academic year 1952-53(3). This plan was to provide the student with 5½ months of continuous service in one general medical clinic to which were attached consultants in all the medical specialties. The planning committee felt that in addition to this, it was imperative that the ambulant patient selected for care in this clinic should have one physician responsible for his total management and that on each of his hospital visits, the patient should come to the same familiar place and see the same familiar and friendly faces. One student was to act as family physician throughout his period of service, calling in consulting help from medical specialties where indicated, extending his services to other family members when needed, and bringing hospital services into the home when it was advantageous. The student's training was to be centered around the care of the individual patient, but would also include scheduled conferences, lectures, and seminars, as well as sufficient free time for house calls and other unplanned responsibilities. Preceptors were assigned to individual groups of 10 or 11 students for seminars which were used for case discussions or didactic teaching.

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² Associate professor, department of psychiatry, University of Oklahoma School of Medicine and University Hospitals, Oklahoma City, Okla.

There were a number of new experiences in this program. Probably the most important was the continuity of contact between the patient and the physician for half a year. It was no longer possible for the student, after examining his patient and attaching the appropriate labels, to refer him to another clinic for treatment, and another student's work-up. The student had to plan his medical management and was forced, sometimes just by repeated contact, into an awareness of the patient's social and emotional needs. He was no longer oriented to disease, but to sick persons, and he began to know the anxieties that ordinarily occur only after he starts his own practice; and the practice of medicine is beset with anxieties.

In this situation the student began to develop attitudes which relieved his anxieties, but were against his patients' better interests. This was partly because he so commonly felt fraudulent in his masquerade as a "real doctor." The student was afraid to say, "I don't know" or to refer questions to others. He felt that the patient was being of more help to him than he to his patient. In defense he sometimes emphasized the technical aspects of his skill, becoming insensitive to or denying the existence of his patients' feelings; he became arbitrary to cover his insecurity; when bewildered by the attitude of the dependent and anxious patient, he was tempted to play the role the patient assigned to him, *i.e.*, the omnipotent father, the unquestioned authority, or the incompetent fumbler. Because of his own ambivalent attitudes toward the role of emotional factors, the conscientious student sometimes put his patient through numerous and exhaustive physical and laboratory studies, only adding to the patient's neurotic body concern. With patients who were hostile, suspicious or questioning, the student felt especially threatened. Not recognizing the psychopathology and defensive maneuvers, he saw but the confirmation of many of his own ideas about himself, his skills, and his status in the clinic.

With 45 students assigned to the clinic at a time, the course became in essence a laboratory in patient management where students began to ask more and more frequently for psychiatric consultation and supervision.

Originally a part-time psychiatrist was

assigned to the Comprehensive Care Clinic to act as consultant and to take part in conferences when his time permitted. Because of the unique nature of this learning experience and its impact on the medical students, it was necessary to increase the amount of psychiatric consultation.

When, in July 1954, full-time psychiatric coverage to the clinic was arranged, it became possible to re-evaluate the needs and goals of the psychiatric teaching program and to plan a curriculum that would best reach these objectives. It is the purpose of this paper to tell the author's experience as psychiatric consultant to the Comprehensive Medical Care Program, and to define further the goals of such psychiatric teaching.

CONTENT AND METHOD OF TEACHING

Since there are psychiatric implications in the care of every patient, the program offered a unique opportunity to the psychiatrist in attendance. He had ideal teaching material: outpatients with a variety of diseases and disorders; patients in whom neurotic problems were more frequent than "psychoses"; patients in whom psychophysiological problems were common; patients who were for most purposes considered to be psychologically "normal"; and patients who were reacting emotionally to physical illness.

The traditional role of the consultant or attending physician in an outpatient clinic is to hear a presentation of the student's history and examination, see the patient briefly, and then discuss treatment. At the beginning of the program, the role assigned to the psychiatrist followed this precedent, and he was called only when the student or the regular doctor attending felt that a psychiatric opinion would be helpful. It was soon obvious, however, that such a plan was insufficient, for a large number of students did not call upon the psychiatrist, while some students became too dependent on him. Although some students were asking for supervision and guidance in their psychotherapeutic relationships with patients, others were avoiding consultation even when it was evident that the patient had an emotional problem. In the purely consultative role, the psychiatrist was not reaching all students. Provisions were made, therefore, to extend

the psychiatric teaching in 2 major ways: by weekly seminars with each group of 11 students; and by making house calls with those students who had patients on home care. These 2 methods were sufficiently rewarding to justify a more detailed report.

SEMINARS

The weekly seminars were informal sessions in which students could bring up current problems in patient management for group discussions. It was soon apparent that the psychiatrist could not depend on the student's ability to carry into general medical work the knowledge and techniques learned in the department of psychiatry during the previous 3 years. Indeed, many students who had performed well in the psychiatric outpatient department seemed unable to do as well in the medical clinic. It was as if they felt comfortable in this sphere only when the patient took the initiative by admitting psychiatric illness. Thus, it was necessary to review briefly previous instruction in basic psychopathology, dynamic structure and function of personality, reaction types, diagnostic entities, and techniques of history taking and psychological examination.

Special emphasis was placed on developing skills in interviewing, and not only eliciting but understanding the primarily vocal communications of patients. Various techniques were tried, such as didactic discussions, interviewing patients before the group and behind a one-way screen, and listening to recorded interviews, combined in each case with group discussion. Students were encouraged to give their individual attention to the patient's story in a noninterrogative way, and without the use of constricting forms or voluminous notes. The students required reassurance that it was neither possible nor desirable to get all the information at the first contact with the patient. This required a revision in many of their ideas of history-taking.

The concept of the psychological examination or mental state was difficult to get across because of the common idea that this was done only with "psychiatric" patients; yet by watching an interview and discussing what they had seen, the students were surprised at the relatively complete and informa-

tive sets of observations that were possible. Many students verbalized their fear of inquiring about suicidal thoughts in the depressed patient for fear of "putting ideas in his mind." Others hesitated to delve into the sexual history because they might get "too deeply" into an unfamiliar area in which they were anxious and insecure. They had a hard time making purely objective and descriptive observations of psychological phenomena. However, by precept and discussion they were able to learn some of the techniques for inquiring into sensitive areas with a degree of objectivity.

There was one approach to the seminars which stimulated interest and participation. This was to present the material as an exercise in problem solving. The essential data were presented to the student in mimeographed form several days prior to the seminar. One such exercise was the following:

You are consulted by a 27-year-old, unmarried, successful attorney who complains of being run-down. He feels he should have some vitamins or a tonic to build him up. You begin to wonder what he means and what he wants built up, for he states that he has felt poorly for only 5 or 6 weeks, and that he has no other symptoms except fatigue and difficulty falling asleep. Past medical history, physical and laboratory examinations are singularly unrevealing. At your inquiry he tells of his engagement to a young woman with whom he is very much in love. As you settle back, preparing to hear the real reason why this patient consulted you, he tells at length of his relationship with his fiancée, extolling her virtues. He talks of his ambitions, both socially and professionally, and how much he is looking forward to their marriage in 2 months. In response to your matter-of-fact questions about his sexual life, he breaks down in tears and shamefacedly confesses that he has attempted intercourse with his fiancée on 2 occasions, but that both times, in spite of strong desire, he was unable to have an erection. In this matter he had experienced tremendous anxiety and guilt. He says, "Doctor, telling you this is the most difficult thing I've ever done. I'm so ashamed. I don't know what you'll think of me."

You ask him about his past sexual experiences. He then settles down to relate his story. His parents, both now dead, were very puritanical, and he had no home instruction in sexual matters because this was taboo. His mother had made him feel that womanhood was sacred, and that sexuality was disgusting. After he had been caught masturbating at age 14, his father had upbraided him, and then warned him that no gentleman ever taken advantage of a woman. He had felt guilty about masturbation after this. In college he had revolted

and had a number of sexual affairs with women of inferior social and educational status. He achieved full physical satisfaction, but always had some guilt and anxiety that he would be found out.

When he met Mary these sexual relationships ceased. He wondered if he would enjoy sexual relationships with her as he had with others. On the occasion of his attempted intimacy with Mary, some 6 weeks ago, he felt like a seducer; Mary was somehow too good for this sort of thing. He began to worry about his own manliness and his fitness for marriage. He felt he might be diseased. He realized he was naive in many ways about sex.

With this confession and increasing confidence, he had many questions: "What is wrong with me physically that I can't have an erection?" "Is it wrong, doctor, for us to have premarital intercourse?" "Should I worry about pregnancy—can you help me on that score?" "Mary seems less anxious and guilty than I, and she seems to be less inhibited. Is that right for a woman?" "I'm also upset, although I don't know why, because she wants the lights on. Besides she asks too many questions, and I'm embarrassed."

Discussion.—Can you answer these questions? How? What is your diagnosis? What is the trouble with your patient? How do you formulate the dynamics involved? What of his relationship to you? What will you do now?

With case material such as this, discussions were enthusiastic and even the more reluctant members of the seminar group could be expected to participate. It was nearly always possible to relate the hypothetical case material to the actual patients for whom the students were responsible, but whose problems they had never discussed spontaneously. Printed case histories designed to raise certain recurrent problems in medical care were brought forth at the request of the students and ranged widely: how to organize time with patients; how to keep accurate and adequate records; how to refer a patient to a psychiatrist; the limits of the physician's responsibility; moral, ethical, legal, and religious questions.

The special advantage of a printed case history offsets one of the major problems in undergraduate psychiatric education, namely, the nature of patient material. In many medical centers students have most, if not all of their patient contacts with the indigent, poorly educated person, eking out a marginal existence in slum areas. The lives of the student's patients are so foreign to his own, and are frequently so overwhelming as to hamper any real understanding between them. It is equally true that when in prac-

tice, he will be dealing with such patients only during the time he devotes to teaching. Albeit artificial, the printed case material can bring to the student, problems much more like those he expects to meet after graduation.

HOME CARE

The home care program is essentially an extension of hospital services into the home environment. It provides an excellent opportunity to help the students understand not only the socio-economic factors which might be operative, but the dynamic interrelationships among the members of a family. One senior student requested help in the management of a 72-year-old Italian immigrant who was dying of widespread metastases from a carcinoma of the prostate. After a period of supportive and symptomatic treatment in the hospital, the patient was discharged to the home care program. It was at the request of his wife, herself a cardiac invalid, and his oldest daughter that he was returned to his home. Soon the daughter, a 35-year-old, single stenographer, approached the student physician on several occasions with complaints about the difficulty in managing the father at home; yet when questioned, she was insistent that he remain there. She said that her father had undergone a decided personality change, and was now demanding, petulant, irritable, and hostile.

Student and psychiatrist visited the home together, where examination of the patient confirmed the history given by the daughter. There was no evidence of underlying organic brain damage, and the behavioral difficulties were felt to be somehow related to the interfamilial relationships. A relatively brief interview with the daughter revealed a significant area of conflict. The father and mother had come to the United States from Italy in their early twenties. They married in this country, and immediately began raising a family. There were 5 children, all of whom were married and away from home except this daughter. She revealed that, pursuant to their cultural custom, she, the oldest child, was selected at birth to remain single and in the parental home to care for the parents during their old age. She was

subsequently taught to do housework and sent to secretarial school, while her siblings engaged in an active social life preparing for marriage. She had accepted her role passively and without question, and was now fulfilling her filial obligation, although not without considerable underlying hostility and guilt, only part of which she was aware. The daughter returned to the hospital on 4 or 5 occasions to see the student in supervised psychotherapeutic interviews, during which time her father progressively improved and became much less of a management problem.

No amount of didactic instruction in the importance of social and cultural factors could have been as important as this one experience for the student.

SUMMARY AND CONCLUSIONS

The concept of a Comprehensive Care Clinic, to which consultants in the medical specialties are attached, is relatively new. The part of such programs that is unique, and has the greatest implication for medical education in general and psychiatric education in particular, is the functioning of the student as a family physician for a period (22½ weeks in the Cornell program, 32 weeks in the Oklahoma program). Such an experience probably parallels the practice of medicine as nearly as is possible during medical school. The importance of psychiatric participation in such a program is obvious and is firmly established.

Since it is so firmly established, there is no need for the psychiatrist to be apologetic about his contribution, and there is no excuse for his allowing it to become a student elective. The medical educator, regardless of his particular field of interest, has the obligation to train physicians in the best way possible. Part of this obligation is to make his subject matter palatable and attractive, but an equally important part is to see that his teaching

reaches and is assimilated by all students under his charge, whether or not the individual student expects to find the subject matter interesting or worthwhile. Possibly there is a place in undergraduate psychiatric education for group psychotherapeutic experiences which are designed to break down the student's resistances, but it can in no way replace organized instruction for which students are held responsible.

It is too early to evaluate completely comprehensive care and training programs and the role such programs should play in the training of physicians. The conclusion of most of those who have participated in them is that they are training better physicians, and as a direct result of this training, leading to better and more complete medical care of patients. Where these experiences are used as a guide to future programs in other schools, it should be emphasized that full-time psychiatric participation in the planning and execution is absolutely necessary in achieving the desired goals.

The psychiatrist can function in a number of specific ways within the clinic setting. He can be available as a consultant for the individual student and his patient, and this will be an important part of his activities. In addition, the curriculum should be so organized that the psychiatrist has time and opportunity to reach all the students. Regularly scheduled seminars with small groups of students, and active participation in the home care program, in my experience are 2 of the most successful means of achieving this goal.

BEHAVIOR SYMPTOMS IN CHILDREN AND DEGREE OF SICKNESS^{1, 2}

JOHN C. GLIDEWELL, PH.D., IVAN N. MENSCH, PH.D., AND
MARGARET C.-L. GILDEA, M.D.³

In planning a comprehensive program in community mental health, the question of defining services suitable to treat certain kinds of mental illnesses in children becomes of paramount importance. Both adequacy and economy of treatment should be constantly kept in mind as checks on the program and its budget, and the constant feedback of these checks should guide the development of the various facilities. For these reasons there is need for reliable screening and a case finding method which has been adequately tested, and which could be useful in making preliminary judgments of the level of adjustment of school children. If this judgment does nothing more than select children who need further study, much will be gained.

Community mental health services may be divided into 4 types, each designed to serve children showing a different degree of disturbance: (1) An educational service to help parents deal with simple maladjustments of their children. These maladjustments show themselves in symptoms which are transient and appear in otherwise well-adjusted children in response to new problems or changes in the environment. (2) A school-centered service which offers help to parents whose children have maladjustments with more fixed and less clearly reactive symptoms, which, however, are not so severe as to disrupt either school attendance or family life. (3) The child guidance clinic which helps the parent and child with problems in which symptoms are fixed and repeated, and severe enough to threaten or

break up school attendance. The family, however, remains intact. (4) Residential treatment is required for children showing problems that lead not only to school disruption, but also to the breakup of the home. These children cannot be adequately treated in school or clinic, but must go to a living-in center which offers 24-hour care (3).

Whether symptoms alone can be used as a screening tool depends on whether they can be shown to be related to the degree of clinical sickness in children. This subject has been much discussed among child psychiatrists for many years. Some child psychiatrists feel that it is dangerous to use presence or absence of symptoms as an indication of whether the child is sick or well. Gardner (5) divides children's problems into two categories, i.e. those requiring short-term therapy, a group which may be equated with Groups 1 and 2, and a group requiring long-term treatment, roughly equal to Groups 3 and 4. Of the former group he says that therapy aimed at relieving the symptom "will probably allow the child an extremely good chance of continuing thereafter a normal and orderly personality development." Of the latter group he warns against using absence or disappearance of symptoms as an indication for stopping treatment, or that the child can be considered well. He says, "removal of the presenting symptom may delay but not prevent the child from developing a more serious disability later in childhood or adult life." Gardner appears to doubt that symptoms themselves can be used to discriminate between sick or well children, or those with different degrees of emotional maladjustment.

On the other hand Levy (7) believes that symptoms can be used to determine sickness or health in children. He says:

One of the findings that resulted from a series of follow-up studies starting at the Institute of Child Guidance in New York and utilizing material from about a dozen child guidance clinics . . . was that the highest correlation with general personality growth was the disappearance of the presenting symptoms. That would be a very important finding

if substantiated—that when the so-called symptoms have been removed, follow-up studies reveal that concurrently beneficial inner changes have taken place.

Witmer (10) also finds that disappearance of symptoms in children treated in a child guidance clinic correlates higher with clinical improvement than any other trait. Kanner (6) says, "the clearing up, or persistence, of the difficulties complained of may frequently, though not always, be used as a measure of the reasonableness and adequacy of the handling of the maladjustment." He lays much emphasis on the "complaint," i.e. the mother's statement of symptoms, as a critical factor in determining treatment.

In 1954, Eitzman (4) found, in an intensive follow-up study of 12 children treated in the St. Louis County Child Guidance Clinic, that mothers reported markedly fewer symptoms and reduced frequency after treatment than they reported at the time the child was referred. Specifically, at the time of referral, the 12 mothers reported a total of 86 current symptoms of 42 different types (mean=7.2). After treatment, these same mothers reported a total of only 40 symptoms (mean=3.3) and only 24 different types.

Although not specifically utilizing mothers' reports of symptoms, a number of studies give attention to the screening of school children for evidence of disturbance. Anderson of the Institute of Child Welfare, University of Minnesota (1, 2) is doing excellent work in screening methods developing a number of instruments which give considerable promise in differentiating children of varying degrees of "adjustment." These instruments, according to Anderson, "were designed for children with enough skill in reading to be able to comprehend the material and enough skill in writing to write something on an open-end sentence test" (2). One advantage of using the mother's report of symptoms is that it makes no demand on the reading or writing skill of the child, and can be used at any age level.

The present study was undertaken to determine whether symptoms in children, as reported by their mothers, could be used to discriminate between those in varying levels of emotional adjustment as independently determined by other means and other observers. The symptoms were compiled in an in-

ventory which recorded not only the type of complaint, but also its severity, frequency and duration.

SAMPLES

School Sample.—This sample consisted of 91 white, public school children in 3 third grade classrooms, 1 in each of 3 schools in St. Louis County. The third grade was selected as showing relatively few transient symptoms of disturbances. Most third grade children have completed the initial behavioral adjustments to the move from home to school. At the same time they have not yet begun to make the transition to preadolescence.

Clinic Sample.—Because the school sample was nearly a typical one, normal, it contained only a few children sufficiently disturbed to require clinical treatment ($n=6$). Because it was so small any result might be due to some special peculiarity of the sample. To have a larger number of disturbed children, an additional 35 were drawn from children referred to the St. Louis County Child Guidance Clinic.

CRITERION GROUPS

In order to test the relationship between a mother's report of symptoms and the sickness of the child, an independent, valid assessment of degree of sickness was required. The following sections describe the method of assessing the degree of sickness.

The Assessment.—All the children in the school sample attended schools in which a psychiatric social worker had been employed for 3 years. During this time the children had been under observation of teacher and worker. In those cases in which they observed problem behavior in preliminary screening, more comprehensive diagnostic procedures were used. Where diagnostic conferences between the worker and the school personnel indicated a possibility of disturbance, the child was referred to the St. Louis County Child Guidance Clinic for diagnostic study. As a result of this screening and diagnostic procedure, it was possible to make an independent professional decision. The school sample included, as would be expected, a large number of children with

no significant mental health problems (Group 1). Teachers were asked to separate these children in 2 groups: 1a, "well adjusted," and 1b, "no significant problems." The result of this additional refinement was a gradation of 4 degrees of disturbance, not including the most severe ones requiring residential treatment (Group 4), of whom none was found in this sample.

Four Degrees of Disturbance.—The definition of the degrees of disturbance follow closely those employed in an early study by Ullman(8). (1a) Well adjusted: A child who is well adjusted in his relationships with others and in his accomplishments. (1b) No significant problems: A happy child who gets along well and accomplishes reasonably well the things that go with his age and level of development. (2) Subclinically disturbed: A child who is not so happy as he might be, with moderate difficulties in adjustment to whom growing up represents a struggle. (3) Disturbed: A child who has, or is likely to have, serious problems of adjustment and needs clinical help.

Children designated as disturbed have been so diagnosed by a psychiatric team in the Child Guidance Clinic. Those designated subclinically disturbed have been so diagnosed after at least a brief diagnostic study at school or in the clinic. Those designated as having no significant problems have shown no evidence of disturbance after 3 years' observation by the worker-teacher team. Those designated as well adjusted were so appraised on the basis of the teacher's observation.

All children in the sample of 35 drawn from clinic records had been given a diagnostic study in the clinic, and the determination of the degree of disturbance was taken from the results of these studies.

Assessment Results.—By this method of assessment, the school sample of 91 included 21 well-adjusted children (Group 1a), 39 with no significant problems (Group 1b), 25 subclinically disturbed (Group 2), and 6 disturbed (Group 3). The clinic sample of 35 children included 2 with no significant problems, 14 subclinically disturbed, and 19 disturbed.

THE INTERVIEW

The mother's report of the symptoms presented by the child was obtained by private

interview in the home. The interview is used as part of a more extensive research and the symptom inventory is only one part. The mother is asked a series of questions about the demographic characteristics of the family and the family background. Next she is asked questions which constitute the symptom inventory. "Does Johnny have any trouble (sleeping, eating, getting along with other children, etc.)?" Affirmative responses are followed by probes into (1) the specific difficulty, (2) its duration, (3) frequency, (4) severity. This kind of questioning is continued through other areas of difficulty. 17 in all: digestion, getting along with grown-ups, unusual fears, nervousness, thumb sucking, overactivity, sex, daydreaming, temper tantrums, crying, lying, stealing, destructiveness, rejection of school.

FINDINGS

The data obtained have been treated by a variety of methods, taking into account the contribution of the variations in sex, age, social class, and schools from which the samples were drawn. In all treatments the findings show a stable and clear-cut positive relationship between the degree of sickness and the number, frequency, duration, and severity of the symptoms reported by the mother. The more symptoms so reported, the greater is the likelihood that the child will be found to be disturbed on clinical examination.

The findings are summarized in Fig. 1, which shows the regression line representing the relationship between the ratings of the degree of disturbance and the mean number of symptoms reported by the mother, in a sample of 126 children. As indicated in Fig. 1, mothers of children without disturbance reported, on the average, about 2 symptoms;

FIG. 1.—Regression of mean number of symptoms reported on degree of disturbance in the child.

mothers of subclinically disturbed children reported about 4 symptoms; and mothers of disturbed children, 6 symptoms.

RELATIONSHIP BETWEEN THE NUMBER OF SYMPTOMS REPORTED AND DEGREE OF SICKNESS

The foregoing summary of findings indicates the general nature of the relationship between the degree of sickness and the number of symptoms reported by the mother. The detailed findings permit elaboration on this relationship, first for the school sample of 91 children, and secondly for the clinic sample of 35 children.

The School Sample.—While the findings show a significant difference among the means of the number of symptoms reported by mothers in the 4 degrees of disturbance, it is important to note the range of symptoms reported by each of the 4 criterion groups. These findings are summarized in Table 1, and shown graphically in Figs. 2 through 5.

The curves in these Figures indicate the details of the relationship. These details are perhaps best summarized by observing that the peak of the curve moves consistently to the right through the 4 groups, from the well-adjusted to the disturbed group. This again shows that the more disturbed the child the more symptoms his mother reports.

These curves, along with the data in Table

TABLE 1

NUMBER OF SYMPTOMS REPORTED BY MOTHERS
(School sample of 91 children)

Degree of sickness	N	Number of symptoms reported (Percentage reporting)				
		0-1	2-3	4-6	7+	Total
		Boys				
1a. Well-adjusted	04	75	25	00	00	100
1b. No known problems.	24	42	25	29	04	100
2. Subclinically dis-						
turbed	14	00	36	64	00	100

Total boys	47	28	30	34	08	100
					</	

1, also show the extent of variation in the symptoms presented by each of the 4 groups. There were, for example, 5 well-adjusted girls (29%) who showed 4 to 6 symptoms, or as many as the average for subclinically disturbed girls. Similarly, there were 2 disturbed boys who showed only 2 or 3 symptoms—too few to reflect the degree of dis-

FIG. 5.—Range of symptoms reported by mothers of disturbed children.

turbance actually found. The findings for these 5 girls and 2 boys reflect the error in this screening device. The effects of the error are discussed in detail in following sections of this paper.

The Clinic Sample.—Because the school sample included only a few disturbed children (25 subclinically disturbed, 6 disturbed), an additional 35 children were drawn from the files of the St. Louis County Child Guidance Clinic. Of these, 2 were found, on clinical examination, to have no significant problems. In both cases the mother reported independently only 1 or 2 symptoms on the inventory. There were 14 children found to have subclinical disturbances, and the mothers of all but 2 reported 4 or more symptoms. There were 19 severely disturbed, and all but one of the mothers reported 4 or more symptoms. These findings show that the results obtained from the school sample were confirmed, and with reduced error.

Extent of Correlation.—The relationship between the degree of sickness in the child and the number of symptoms reported by the mother can be represented by a correlation coefficient of 0.50, shown graphically by the regression line in Fig. 1.

Reliability.—These findings show a positive and reliable relationship between the number of symptoms reported by a third-

grade child's mother and the degree of sickness found in the child on clinical examination. The prediction of the degree of sickness from the mother's report has been shown to have some error (10 deviant findings out of 126), but all the differences among mean number of symptoms reported for children showing 4 degrees of disturbance were statistically significant at the 0.01 level of confidence (see Tables 2 and 3).

CONTRIBUTION OF THE FREQUENCY DURATION, AND SEVERITY OF THE SYMPTOMS REPORTED

The findings discussed have been confined to the number of symptoms reported

TABLE 2
MEAN NUMBER OF SYMPTOMS FOR BOYS AND GIRLS WITH FOUR DEGREES OF DISTURBANCE

Degree of disturbance	School sample of 91			School plus clinic sample of 126

* Not significant.

by the mother without regard to her report of their frequency, duration, or severity. The data were treated so that a score was derived for each symptom reported. The score was a composite of 3 ratings by the mother: one for frequency, one for duration, and one for the severity of the symptom. The scores for each of the 17 symptoms were then added to yield a total for the entire symptom inventory. This total took account of the frequency, duration, and severity of the symptoms as reported by the mother. These totals were then given the same treatment as the number of symptoms reported, and the results were compared to determine if there was an increase in the sensitivity of the symptom inventory as an index of disturbance.

When the frequency, duration and severity of the symptoms reported by the mother were thus taken into account, the resulting symptom inventory scores provided a more sensitive differentiation of disturbance in third-grade children than did the simple count of the number of symptoms.

Differentiating Power of Individual Symptom Areas.—It was found that each of the 17 symptoms was reported more often for disturbed than for undisturbed children, although not always significant at the 0.05 level of confidence. The symptoms which appeared significantly more often in the disturbed boys

were: sleeping trouble, trouble getting along with other children, nervousness, unusual fears, and stealing. Those symptoms which appeared significantly more often in the disturbed girls were: sleeping trouble, lying, and making a fuss about going to school.

DISCUSSION

The foregoing sections present data to confirm the hypothesis that a symptom inventory can be used for screening children for psychiatric difficulties. The findings show a reliable and positive relationship between the number, frequency, duration, and severity of symptoms reported by a child's mother and the degree of disturbance found in the third grade child. They also show that prediction of disturbance from the mother's report is imperfect. The discussion of these findings is best stated in terms of the actual degree of success one would have had in predicting disturbance in these children from the reports of symptoms by the mother.

There are essentially 3 types of screening objectives for such an instrument as this symptom inventory: (1) prediction of *both* the presence and the absence of disturbance; (2) prediction of the *presence* of disturbance in the child—when can one be most sure that he is disturbed? (3) prediction of the *absence* of disturbance—when can one be most sure that the child needs no psychiatric attention? The success in achieving each of these objectives is discussed below.

Maximum Success.—If one wishes to maximize the success in predicting both presence and absence of disturbance, one must set a critical score near the middle of the range. In this case one would set the critical score at 4 symptoms. If the mother reports 4 or more symptoms, one would predict disturbance; if the mother reports fewer symptoms, one would predict no disturbance. Applied to these data, such predictions would lead to 12 false positives, 18 false negatives, and 61 correct predictions, or a 67% success predicting both presence and absence of disturbance.

Predicting Presence of Disturbance.—If one wished to be sure that a child was disturbed, he would select a cutting point near the high end of the scale. In this case success would be measured in terms of the num-

ber of false positives, or the number of times the children selected were found, in fact, not to be disturbed. In such a case, one would set the critical score at 7 symptoms, and he would predict that all children whose mothers report 7 or more symptoms will be disturbed. Applied to the school sample, such a prediction would lead to 1 false positive in 7, or about 86% success.

Predicting Absence of Disturbance.—If one wished to be sure that a child was not disturbed, he would select a cutting point near the low end of the scale. In this case success would be measured in terms of the number of false negatives, or the number of disturbed children not included in the group screened as possibly disturbed. In such a case, one would set the critical score at 2 symptoms, and he would predict that all children whose mothers report fewer than 2 symptoms were clear of disturbance and need not be examined further. Applied to the school sample, such a prediction would lead to 2 false negatives in a total of 23, or about 91% success.

A second measure of success by this last method, the most typical of public health activities, is the percentage of actually disturbed children who are "missed," or not included in the group screened as needing further examination. Applied to the school sample, this prediction would result in the omission of 2 in 31 disturbed children, or about 93% success.

SUMMARY

Data have been presented to show that, in a sample of 91 school children and a sample of 35 clinic cases, a reliable, positive relationship exists between the number, frequency, duration, and severity of the symptoms reported by a child's mother and the degree of sickness found in the child. The relationship permits one to use the mother's report as a screening instrument with more success than with most medical screening techniques.

NEUROPSYCHIATRIC ASPECTS OF ACUTE POLIOMYELITIS^{1, 2}

JIMMIE C. B. HOLLAND, M.D.,³ AND MARTIN R. COLES, M.D.⁴

The epidemic of poliomyelitis in Boston in 1955 provided an opportunity for extensive studies of the course of this disease. Unusual psychological phenomena which occurred in acutely ill patients were quickly brought to the attention of the psychiatric staff at the Massachusetts General Hospital. A cursory survey of the literature disclosed few clinical studies of the neuropsychiatric aspects of acute poliomyelitis (1, 2, 3, 4). This study was designed, therefore, to investigate the delirium observed in several patients, the psychological impact of an acute and crippling illness, and the possible role of a psychiatrist in the management of this disease.

MATERIAL AND METHODS

One hundred and eight hospitalized adult patients were interviewed. Of these, 46 were in respirators, and they were interviewed repeatedly for periods up to 6 weeks. Of the remaining 62 nonrespirator patients, 48 suffered from varying degrees of paralytic poliomyelitis and 14 had nonparalytic poliomyelitis. The 62 patients in the nonrespirator group were interviewed only once unless there was therapeutic reason for additional interviews. The age range of the patients was from 15 to 58 years, and 78 percent were between the ages of 20 and 35.

The interview technique was modified, when necessary, to comply with the severity of the illness. The interviews, one-half to 1 hour in length, included a description of mental status: general behavior, stream of thought, mood, content of thought, orientation, memory, insight, and judgment. They

also included a brief social history and an attempt to assess the patient's emotional response to his illness. It soon became apparent, however, that it was necessary to modify this technique for the respirator patients. Interviews were usually limited to 5 to 15 minutes. The psychiatrist wore a mask, and in those cases where a tracheostomy had been performed it was necessary for the interviewer to cover the end of the tube with his finger to enable the patient to speak. The only way the sick person could see the psychiatrist was through the mirror at the head of the respirator. Even these brief interviews were frequently interrupted by mechanical aspiration of the tracheostomy tube, adjustments inside the respirator, and by rapid fatigue of the patient. Although the interviews were brief, they were sufficient to establish the presence or absence of delirium, to assess the patient's psychological reaction to the respirator, and to approximate his mood. When delirium was present, disorientation, confusion, thought content, mood and sensorium were described as well as possible. When a patient's physical and mental state permitted, interviews were allowed to become psychotherapeutic. The investigation of most respirator patients included some contact with persons who were close to them. Relatives, nurses, physicians, and clergymen were interviewed. Throughout this study the same 2 psychiatrists conducted the interviews. The first few patients were interviewed by both together in order to assure a similar interview technique in this unusual situation.

OBSERVATIONS

Delirium.—In 17 patients we observed a transient delirium. Of these, 15 patients were in respirators. One patient had bulbar signs but was not placed in a respirator, and another developed his delirium before a respirator was used. All patients were in the acute febrile phase of poliomyelitis at the onset of the delirium, and all showed neurological signs of bulbar or bulbospinal involvement. The delirium occurred early in the hospital

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

³ Present address: 302 Crosby Blvd., Buffalo 21, New York.

⁴ Massachusetts General Hospital, Boston, Mass.

course, varying from the first to the 11th day after admission. In the 15 deliria observed after confinement in a respirator, onset was on the first to the 10th respirator day. In 2 cases, the delirium and confusion were part of a steady downhill course leading to coma and death. Seven patients became comatose, but recovered. Three of these had severe but short episodes of hypoxia caused by retention of tracheo-bronchial secretions or by mechanical failure of the respirator. Eight patients never became comatose. We were usually able to fix the time of onset of delirium within a matter of hours, but inasmuch as the sensorium cleared gradually the exact duration of the delirial state was difficult to determine and has been arbitrarily chosen. It appeared to vary in length from as short as 5 days to as long as 6 weeks; the average time was about 2 weeks. In general, the delirium disappeared at the time the patient became afebrile, or shortly thereafter.

Delirious patients showed a fluctuating level of consciousness from one interview to another and even within the course of a single short interview. At times they were clear, alert, and oriented; at other times incoherent, drowsy, and confused. Restlessness and excitement were occasionally observed. The span of attention was short and both recent and remote memory was often grossly impaired. Two patients had a history of gross psychiatric difficulties prior to their attack of poliomyelitis, but no qualitative differences could be noted between their delirium and that of the other 15.

Thought content was frequently related to sounds and objects of the environment which were misidentified and falsely interpreted. At times frank delusions and visual hallucinations appeared; a subtle shading between illusions, delusions and hallucinations made classification difficult. The delusions and hallucinations were usually concerned with pleasurable experiences, such as being at home, riding in an automobile or plane, or taking a boat trip. They frequently involved motion of some type. An occasional patient took his respirator with him on his imaginary flights. Sometimes a patient described his hallucinations as if they were vivid dreams which he recognized as such, but at other times they were entirely real to him. Such

hallucinatory experiences seemed to be enjoyable rather than disturbing and were accompanied by a pleasurable affect. They occurred most frequently at night but also at other times when the patient was falling asleep.

A few patients, at one time or another, had frightening illusions or hallucinations. We also observed occasional evidence of anxiety, apprehension, fear of being harmed, and accusatory attitudes toward the ward personnel, sometimes of blatantly paranoid nature. All patients who survived their illness recovered from the delirium. Gradually they had fewer imaginary experiences and progressively longer periods of lucidity until a sustained normal mental status was restored. As patients improved, however, many exhibited concern over their "strange behavior," which they recalled vividly, and expressed fears of "losing their minds."

A clinical picture of the delirium is illustrated by the following cases:

Case 35.—B.D., a 34-year-old white married engineer, the father of 4, entered the Massachusetts General Hospital on August 7, 1955, with paralytic poliomyelitis. One day before admission he complained of headache, backache, and abdominal distress. On the day of admission, his family physician had discovered a stiff neck. At that time the patient complained of frontal headache, photophobia, intense low back pain, chills and fever. The cerebrospinal fluid contained 240 white cells. By afternoon of the day of admission he had developed intercostal, diaphragmatic, and bilateral leg and arm weakness. He was placed in a respirator and a tracheostomy was performed. Intravenous fluids were given and a nasogastric tube was inserted. The patient was hypotensive for 2 days and levarterenol (Levophed®) was administered. Five days after admission, he was oriented and alert. He was still febrile (101° to 102°) and his medical prognosis was considered poor. He was first seen by one of us (R. C.) on the 11th day of hospitalization. The nurses' notes revealed that he had fluctuated between being unresponsive and being rational and clear during his second hospital week. In an interview lasting 15 minutes, the patient was cooperative in explaining that he had been "hallucinating." He talked about driving his family to a friend's house at the beach, and stated that he always drove to places "out of the hospital." He said that he knew these thoughts were absurd, "but still I go." He said that this had been occurring 2-3 times a day but now only once a day. Memory of recent events was vague. He reported that he was cheerful most of the time and that "prospects looked good." When he came in he was "quite sick," but now was "better" and all would "turn out right in the end." He

respirator. He declared that time was very unimportant and that he was "not worried about something to occupy my mind." He had several medical complications which resulted in some temporary "blue periods" but his general optimistic outlook and assurance that he would soon be well persisted. He later demonstrated the use of portable respirators to new patients, and his cheerfulness and encouragement were a source of support to others.

Case 27.—D.C., a 23-year-old unmarried Mormon missionary, was placed in a respirator on September 1, 1955, because of rapidly progressing bulbospinal poliomyelitis. When seen by an examiner (R.C.) the following day, she was alert, smiling, and talkative, and stated a strong dependence on her religion for "keeping me cheerful through it all." She was not depressed and was confident that being in a respirator was "only a phase." There were no signs of a delirious state. Although her condition was precarious for over a week, each day she would tell the examiner, "I am nearer to getting better." She would smilingly and repeatedly talk about the most morbid aspects of her disease with no evidence of sadness or fear. On one occasion she told the examiner, "My lungs are dead, but it is only a matter of time and prayer." Over a 6-week period, her physical state remained unimproved, but her buoyant spirits persisted. On several occasions, the patient remarked how fortunate she was to be less seriously ill than others. On later visits, although she had made no progress toward recovery from the severe muscular and respiratory paralysis, she was still firmly confident of eventual full return to health.

Response of Paralytic Patients.—A variety of psychological mechanisms were observed in patients with paralytic disease. Of the 48 paralyzed nonrespirator patients seen, well over half demonstrated rationalization and denial. Rationalization was evidenced by: "This has been an interesting and valuable experience," or "I am lucky now to have immunity." Denial was stated in phrases like: "Though my legs are paralyzed today, I expect to be back to work soon." Patients who obviously would require crutches and braces to walk talked of being up and about and of returning to work in the near future. At the time they seemed unable to accept a more realistic view of their disability. Some patients described their paralysis as "minimal" or "very slight" in definite contradiction to their true status. In many of them, however, crying and signs of depression occurred when the first attempts at physiotherapy forced them to recognize the reality and extent of their paralysis. Despite repeated requests for reassurance early, patients often became angry with their doctors later, for

what they then felt had been deception about the eventual outcome of their paralysis. Many patients made references to the illogical and whimsical vagaries of Fate, with lamentations such as "Why did this have to happen to me?", "What did I do to deserve this?", and "Bad things always happen to me."

In the paralyzed group, evidence of psychological regression was most frequent in those who were severely paralyzed. One young woman who had been transiently in a respirator said on several occasions, "I'd rather be upstairs in a respirator where I got more attention." Another woman with severe bilateral leg paralysis, a formerly self-sufficient instructor of physical education, quickly regressed to a demanding, petulant individual who threw objects at the nurses during temper tantrums. In some cases, by contrast, the disease was looked upon as a challenge. Frequent references were made to "licking polio" and "fighting the disease," as if the acute course of the illness could be altered by strong exercise of will.

Response of Nonparalytic Patients.—Patients with nonparalytic poliomyelitis were not severely ill medically and showed no evidence of delirium, denial, rationalization or regression. Nonparalyzed patients who were seen early in their illness were anxious and apprehensive about the future course of their disease. They knew they were on a special ward for poliomyelitis where others about them were developing paralysis or respiratory distress. Symptoms and possible outcomes of poliomyelitis were frequent topics of newspaper articles and conversations among the public, and information about poliomyelitis became common knowledge during the epidemic. The dread and fear generally present in unafflicted people in the community were intensified in the patient whose condition might change rapidly, whose outcome was uncertain.

Some patients, whose poliomyelitis at no time resulted in paralysis, and who left the hospital essentially well, were interviewed just before discharge. They were exuberant and happy about their recovery without paralysis. They considered themselves fortun-

nate to have escaped more severe manifestations and residua.

DISCUSSION

DELIRIUM

The transient delirium observed in the 17 patients with bulbar or bulbospinal poliomyelitis presented a strikingly uniform picture. It occurred in such seriously ill patients that they might not have survived without the recent scientific knowledge available, and the expertness of the medical care they received. The paucity of earlier reports of a delirium in poliomyelitis may reflect this fact. Some had, in addition to spinal and bulbar signs and delirium, coma and convulsions, indicating extensive and diffuse involvement of the nervous system. We shall consider the delirium apart from this larger clinical picture.

The delirium was not unlike that described in several other neuropsychiatric conditions. Withdrawal from barbiturates, bromide intoxication, alcoholic hallucinosis, and the encephalitic picture associated with certain poisons and toxins have been described to produce similar clinical pictures. Confusion, a clouded sensorium, and hallucinatory experiences similar to those described in the case presentations are common to deliria resulting from various etiologies. In the delirium we observed, the imaginary experiences at times appeared to be hallucinations, at other times delusions or illusions. Several salient features, nonetheless, seemed typical of this particular delirium. Patients usually had a clear memory of their imaginary experiences and within minutes could explain with clarity and insight that a "dream" had occurred. The experiences were usually pleasurable and nonfrightening. The sensation of motion was common. The term "traveling psychosis" arose from the frequent automobile, plane, and boat trips on which patients thought they embarked. We suggest the possibility that in his toxic state, a patient might misinterpret the constant whir of the respirator motor accompanied by the rhythmic motion of the air about his body as a sensation similar to riding in some type of vehicle. At times the illusory quality was even more pronounced when a patient incorporated parts of the res-

pirator into the travel dream. We are impressed that previous personality apparently did not bear a relation to the occurrence of the delirium. Indeed, recovery was complete in all patients who survived.

In 1884, Strümpell used the term poliоencephalitis for what is generally conceded to be the initial description of bulbar poliomyelitis(5). Previously, poliomyelitis had been recognized as a disease of the spinal cord only. Since then, neuropathological studies have indicated that nearly every part of the central nervous system can be damaged. Patchy lesions of medulla, pons, cerebellum, mesencephalon, diencephalon and cerebrum, in addition to lesions of the spinal cord, have been noted in histologic studies (3, 6, 7, 8, 9).

It is appropriate in a diffuse disease of the central nervous system to attempt correlation of known pathological lesions with the occurrence of particular symptomatic manifestations, *e.g.* delirium. Lesions of the cerebral cortex are usually inconspicuous except for the precentral gyrus which may be extensively involved. No constant lesions of any other cerebral areas have been described. Lesions of the diencephalon, particularly the hypothalamus, have been reported in as high as 85% of cases of bulbar poliomyelitis(8). The occurrence of disordered sleep patterns, gastrointestinal disturbances, and alterations of blood pressure and temperature as probable clinical representation of hypothalamic lesions lend substance to the possibility that emotional instability could also be associated with lesions of this area. Involvement of the midbrain was found in all 111 autopsied patients who died of bulbar poliomyelitis in the Minnesota epidemic of 1946(9). Lesions of this area from other causes have a demonstrated association with delirium: Wernicke's hallucinosis and in some instances, barbiturate intoxication or withdrawal. L'Hermite has reported cases of hallucinosis related to occlusive vascular lesions of the mid-brain which he called peduncular hallucinosis(10, 11). These patients described pleasant dream-like visual hallucinations into which they had insight. Though his conclusions have been questioned, the clinical phenomenon he described resembles that seen in the deliria of our patients with poliomyelitis. In addition, however, we noted confusion, dis-

orientation, and an altered state of consciousness. The association of clinically recognizable bulbar dysfunction in each of our patients with delirium supports, by anatomical proximity, the possibility that pathological lesions of the brain stem may be causally related to the delirium, though it is impossible to delimit a particular area. Pathological studies of the brains of several patients in this report are in progress (12).

The presence of fever, at times of hypoxia, and the effects of medications are additional recognizable factors which might have been etiologically related to the delirium. Deliria occasionally occur during febrile states accompanying other systemic infections. Though clinically these patients did not show more than transitory bouts of hypoxia, unrecognized or sub-clinical hypoxia and even hyperventilation in the respirator must be considered as potentially having occurred. Though drug administration was kept to a minimum, sedatives were occasionally given in small doses.

Purely psychological factors which could account for delirium in the absence of any specific brain lesion must be considered. The work of Hebb and his group (13, 14) which demonstrated that isolation of normal individuals under special conditions can produce psychotic states has been considered by others to be relevant to the genesis of the deliria seen in respirator patients with poliomyelitis (15). Serious illness in a respirator imposes great stress on an individual. Perhaps this stress might have produced a psychotic-like state in some of our patients. For the most part, our patients had motor paralysis or paresis from the neck down; their sensory perception was, however, completely intact. They complained frequently of pain and discomfort. They were not isolated. They were spoken to every half hour by a polio team physician during their critical stage. Twenty-four hour lights, nursing activities, and ward noises produced environmental stimulation. This marked difference from the experimental environment created by Hebb where deprivation of visual and tactile stimulation are essential leaves few similarities with which to support a pathogenesis by analogy.

PSYCHOLOGICAL RESPONSE TO ILLNESS

Denial was the one psychological mechanism seen in the vast majority of paralyzed patients which appeared to bear a direct relationship to the severity of illness. Denial was not seen among non-paralyzed patients. We may speculate that there was little need for such a mechanism in these patients, since most of them were not severely ill. In this study it seemed that overwhelming illness was requisite for use of the mechanism of denial. Denial was a universal reaction in the respirator patients, and became pervasive enough to convey a sense of cheerfulness and confidence at startling variance with the distressing medical facts.

Rationalization, like denial, was seen in many patients, but seemed to be a less rigid and less extensive mechanism. It was particularly common among patients who were not seriously ill. It is of interest that 2 severely ill respirator patients used little denial or rationalization. Each talked intermittently about the possibility of death and the actual severity of his illness. They were the 2 oldest patients in the series, a man and a woman, each over 50.

Certain differences in psychological reactions between the patients in respirators and those with paralytic poliomyelitis who were not in respirators were particularly noteworthy. Whereas the paralytic patients were able to indulge in long range planning, those in respirators concerned themselves with immediate needs and desires. When asked what they thought about, they replied in terms of respirator care, suctioning of the tracheostomy tube, and maintenance of respiratory function. To these patients life had become dependent upon a mechanical device; cessation of its function would entail immediate death. The integrity of the electric circuits, the presence and competence of nursing personnel, and the efficiency of the respirator loomed as the very links between them and life. And, indeed, these links were often realistically threatened. In several cases, for example, electric plugs accidentally were kicked out of sockets, or portholes were left open. In either situation it might have been impossible for the patient to summon help

in time. Such experiences led to overwhelming anxiety, fear, and dread of repetition. Moreover, the emotional impact of repeated hurricane warnings, common at that time in Boston, was considerable because of the possible threat to electric power.

From their first encounter with it, the respirator presents a special problem to patients which is usually marked with anxiety. Here were people whose increasing respiratory distress demanded their adjustment to a fearsome mechanical device, with its attendant implications of critical illness, that they might be given an external force for life's breath itself. Once adjusted to the respirator, however, psychological dependence upon it became marked, often in excess of the actual physical need. Such need for this machine appeared to corroborate Seidenfeld's observation of the similarity to an addictive process(16). It was necessary to plan gradual removal from the respirator, despite good respiratory function, because of a patient's fear of relying solely upon his own breathing. Patients frequently were alarmed during the first few minutes out of the respirator and had to be constantly reassured that they were breathing adequately. As might be expected, complete dependence upon external forces for breathing, eating, elimination and the maintenance of life fostered childlike regression in some patients.

Sustained depression was not consistently observed in any of the respirator patients, but depressive symptoms did occur transiently in the evenings. We believe this may be interpreted as a temporary breakdown of the denial mechanism. In marked contrast to these occasional periods of gloom was the more profound depression seen in the paralytic non-respirator cases which occurred much earlier in their illness. Often it was related to the start of physiotherapy and the consequent necessity to recognize and accept their actual disability. Here, depression might have been an intermediate stage in the progression from denial to adjustment to the disability. Later, in the rehabilitative phase and thereafter, it seems that previous personality determines each patient's lasting response to his disease(17).

ROLE OF THE PSYCHIATRIST

In this study of 108 patients of varying socioeconomic backgrounds, we were surprised by the absence of negative attitudes towards being seen by a psychiatrist. Many patients enthusiastically welcomed our visits. Interviews offered them an opportunity to express their fears and anxieties. They were unable to express these feelings to their families or to a medical and nursing staff with little time to listen. A real need existed for a person with whom they could discuss the emotional impact of their illness. Although consultation regarding serious psychiatric problems in a few patients helped to initiate this investigation, it soon became clear that the majority of patients had substantial emotional problems related to the illness legitimately within the purview of a psychiatrist. With a psychiatrist on a hospital polio team certain predictable difficulties in treatment, management, and rehabilitation were anticipated, and in some cases, expeditiously handled. In addition, psychiatric consultation with the families, in some instances, helped them to adjust to the serious illness and long rehabilitation of their relatives.

The polio nurse requires training in the special emotional problems involved in the care of these patients, and this is best provided by a psychiatrist working with the team. Finally, arrangement of respirators in compatible social groupings so that patients can maintain each other's morale might best be done by a participating psychiatrist.

SUMMARY AND CONCLUSIONS

1. A neuropsychiatric study of 108 hospitalized patients with acute poliomyelitis was made during the Boston epidemic of 1955. Of these, 46 patients were in respirators, 48 had paralytic poliomyelitis not requiring a respirator, and 14 had non-paralytic poliomyelitis.

2. A delirium was observed in 17 patients who were acutely ill with bulbar or bulbo-spinal poliomyelitis. This delirium was characterized clinically by a varying level of consciousness, pleasurable hallucinatory experiences and frequent illusions and delusions. There was waxing and waning of disorienta-

tion and confusion with a shortened attention span. Imaginary experiences were often described by patients as "wakeful" or "vivid dreams." The delirium occurred with the acute toxic phase of illness and lasted an average of two weeks followed by complete recovery in those patients who survived.

3. Psychological responses to acute poliomyelitis were studied in an attempt to delineate specific mechanisms involved. Rationalization, denial, and regression were often observed and have been described. The occurrence of anxiety and depression at various stages of the disease is noted and discussed.

4. The role of a psychiatrist as part of a hospital polio team is emphasized (5).

DISCUSSION

JOSEPH S. BIEMAN, M. D. (Baltimore, Md.)—Acute, major, and crippling diseases have been intensively studied from the medical and physiological point of view, with only very little attention until recently to the psychological impact of the sudden

physical traumata. Antibody response and pleocytosis of the spinal fluid are thought of as immediate defensive reactions of the body to the invasion by the poliomyelitis virus, but, as Drs. Holland and Coles have demonstrated, the affected patients have other defensive reactions on an ego level that are probably just as necessary for survival.

The large number of patients studied, representing different types and degrees of severity of poliomyelitic involvement, afforded a good opportunity which the authors capitalized on quite successfully for comparative observations concerning the use of denial as a defensive reaction in the acute stage of the illness.

Denial is an ego defense mechanism designed to ward off or change an unpleasant or painful external reality. The use of denial by fantasy, words, or acts is accepted as something quite necessary and appropriate for the very young child. This, of course, is not true for the adult who, when he denies the obvious, is immediately considered to be at least unrealistic. But perhaps the poliomyelitic adult *needs* to be, since reality here, as represented by motor paralysis or imminent death from respiratory failure, may be too overwhelming. Overwhelming in what way? What would happen if the use of denial were not possible; what purpose does denial serve? The authors have speculated that depression is the intermediate phase between denial and acceptance of the illness. Perhaps another possibility is that denial is, in a manner, a defense against the depression which may come all at once if the illness and its implications were accepted and allowed rapidly to lower the self-esteem of the patient. Denial would defend against depression by nullifying the loss of self-esteem.

One very interesting finding was the difference in the degree of denial used by respirator and non-respirator paralytic cases. The respirator patients had a denial in affect also, as evidenced by their unexpected cheerfulness. The denial seems to be more complete. It seems permissible to speculate that the denial in affect is a defense against an underlying depression. The more immediate and everpresent threat of a respiratory death may make this completeness more necessary than in the paralytic cases. One also wonders whether the physical and psychic regression enforced by being in the respirator might not facilitate the use of denial.

It has been quite interesting to compare the reactions of adults with those of the children aged 4 to 12 with lower extremity involvement whom we have studied in an interdisciplinary research project at the Psychiatric Institute of the University of Maryland under the direction of Dr. Jacob Fine-singer.

Denial was used by these children quite extensively and in varied forms. In some cases the illness itself was denied. One 6-year-old boy said that in the winter he would think about getting cancer and in the summer he would think about getting polio. He had been afraid of getting polio because there were several kids in the neighborhood who had it and now he was not taking any chances on catching it himself. The boy talked about this in

* The authors wish to express thanks for the advice of Drs. Erich Lindemann, Carl Singer, Stanley Cobb, John Nemiah and Peter Sifneos.

a cut and dried way without affect. An 11-year-old boy, looking quite frightened, at first said that he felt "all right," and then went on to state only that he "might have polio" and he doesn't "want to think about it." One might say that he was denying his illness by making the diagnosis a "might" or "maybe" one, and only a possibility instead of a reality. The denial of the severity of the illness is illustrated in the remarks of an 11-year-old girl. Being in the hospital and not able to go outside didn't bother her since she knew she was going to get well. Another 11-year-old girl at first smiled quite sweetly in response to questions about how she felt when she found out she had polio, but only minutes later she unsuccessfully tried to cover up her tears with this smile while talking about the same subject.

As these children were followed from the acute through the convalescent period, the use of denial by fantasy of the loss of motility became quite evident. For example, one boy in play fantasied himself turning into Superman who then flew around. This same boy would sing about Davy Walker instead of Davy Crockett. Material like this leads one to speculate as to whether the content of this very interesting "traveling psychosis" may not be, in part, a denial by fantasy of the extreme immobilization of the respiratory patient. The almost complete lack of relevant literature on the psychiatric reactions of acute poliomyelitis patients reveals the distance the psychiatrist has stood from the acute infectious disease ward. Dr. Holland and Dr. Coles have helped place him on this ward by the bedside and by the respirator.

ADMINISTRATIVE PSYCHIATRY

A NEW FIELD—CHALLENGING AND REWARDING

WILLIAM B. TERHUNE, M.D.¹

The physician, whether he is in private practice, in a group organization, or in a hospital position, is doing some administrative work. It is not generally realized that the intern, the resident, the ward physician, and the chief of a service, all have some administrative duties and should understand the basic principles of administrative procedure. Some training in administration should be a part of the under-graduate medical program. The hospital superintendent, the recognized administrator, must of course be well grounded in this field(8, 14).

Up to a few years ago, physicians generally felt that administration was unrelated to their major concern—the care and treatment of patients. Institutional administration, specifically in hospitals, was considered a matter of budgets and red tape, of political finessing and compromises, a chore to be done by “the other fellow,” if possible. It was perhaps natural that this view was held by psychiatrists and persons preparing to be psychiatrists. Modern emphasis on the individual treatment of mental illness and on the doctor-patient relationship casts administration in the role of merely facilitating treatment. It is recognized today, however, that it is in itself a therapeutic tool, a part rather than an adjunct to treatment(15).

The most important single factor in the efficacy of treatment in a mental hospital is the intangible element that can best be described as “atmosphere,” according to the findings of a committee of psychiatrists which met under World Health Organization auspices in 1952 to consider the essential elements of adequate mental hospital care. “The mental hospital’s role,” the committee’s report states, “is that of a therapeutic community. As in the community at large, one

of the most characteristic aspects of the psychiatric hospital is the type of relationship between people that is to be found within it. The nature of the relationships between the medical director and his staff will be reflected in the relationship between the psychiatric staff and the nurses, and finally in the relationship not only between the nurses and the patients, but between the patients themselves(16).”

Implicit in this atmosphere and in these relationships is effective administration. Let us see why this is so. “Treatment in the mental hospital,” according to a 1947 statement by the Group for the Advancement of Psychiatry, “is regarded as a total institutional process, rooted in medical responsibility, but with psychiatrically oriented participation by every staff member, each contributing to the total process on the basis of clearly established administrative allocations of responsibility and of well-grounded and disciplined professional attitudes(5).”

Note the words “clearly established administrative allocations” in the above statement. The mental hospital’s administrative structure must carry out the objective of improving the individual patient’s condition as speedily as possible. The hospital’s facilities and the services of its personnel must be coordinated through effective administration, so that they constitute a unified instrument of treatment and rehabilitation(15).

Viewed in this way, administration is not something divorced from and opposed to clinical psychiatry. Since good administration is, in essence, good interpersonal relations, it calls for therapeutic skills of a very high order(12). I believe that if residents in psychiatry are brought to understand these aspects of administration, they will be eager to enter this comparatively new and challenging field.

The basic principles and procedures of administration that have been developed by industry are applicable to administration in hospitals and other medical groups. In brief,

¹ Chairman, Sub-Committee on Education and Training, Committee on Certification of Mental Hospital Administrators, American Psychiatric Association; Medical Director, Silver Hill Foundation, Inc., New Canaan, Connecticut; and Associate Professor of Clinical Psychiatry, Yale University.

administration consists of deputizing, authorizing, and supervising. The first 2 functions call for initial action that is decisive and thoughtful. The right people must be chosen—people capable of carrying the responsibilities deputized to them; and they must be given authority commensurate with these responsibilities. The third function, supervising, is a continuing one that presents the main problem in administration. It is based on a free flow of information from the top echelons to the lowest levels of the organization, and from the lowest to the top. There must be a 2-way flow, up and down the ladder of organization, and also a horizontal flow (if one may use such a term) between branches of the organization at various levels (1, 8).

Communication, it has been said, is the heart of good administration. The most effective means of communication are face-to-face and group discussions. The findings of social science have shown over and over again that understanding and compliance are greater when information is derived from group decisions rather than from directives and orders superimposed from above. Written data—memoranda, manuals, posters, and bulletins—should be thought of chiefly as a means of recording decisions arrived at through conferences and group action (8). We touch here upon many factors that are of interest to the psychiatrist; unfortunately, they cannot be discussed at length in this paper.

These general principles and procedures of administration are applicable in any organization. Nevertheless, the analogy between industrial and medical administration must not be pushed too far. Considering specifically the mental hospital, the "product" is the patient and his recovery. Obviously, it cannot be turned out on a mass-production basis; it must be "crafted" to individual needs. The motive is the maximum improvement of the patient, whereas in industry the motive is profit (8).

As a matter of fact, the application of administrative principles and procedures is not identical in a general hospital and a mental hospital. For this reason, The American Psychiatric Association came to realize that standards and certification procedures should be set up for mental hospital administrators,

in line with the trend in training courses and certification for general hospital administrators (11). This view was "without prejudice" to the many superintendents who have been trained by precept and experience, and are serving as able administrators. More formal and adequate methods of training are needed today (12). A permanent Committee on Certification of Mental Hospital Administrators was established by The American Psychiatric Association in 1953. In addition to setting up standards, evaluating the qualifications of candidates for certification, and issuing certificates, the Committee was empowered to advise on courses of study and technical training in this field and to distribute information that would promote the fitness of persons wishing to qualify as mental hospital administrators (3).

Under the impetus of the Committee's activities, and also because of the growing awareness of the importance of administrative psychiatry, training courses have been established at the Menninger Foundation, Columbia University and the University of California; and others are in the planning stage.

A study is now being undertaken at the Yale University School of Medicine to ascertain the specific requirements for training in administrative psychiatry, and to determine the best pedagogical procedures. This study, covering a 5-year period, is sponsored by the Yale School of Public Health, Section on Hospital Administration, the Faculty of Psychiatry, and the Connecticut Department of Mental Health, with assistance of funds provided by the National Institute of Mental Health.

The course at Columbia University, which opened in the fall of 1956, is cooperatively administered by the University's School of Public Health and Administrative Medicine and the Department of Psychiatry of the Faculty of Medicine with consultation and participation in the teaching program by the New York State Hospital Service and The American Psychiatric Association.

The curriculum time, totaling 20 months, is divided into 4 sections, leading to a Master of Science degree in Administrative Medicine: Basic courses in the School of Public Health and Administrative Medicine, courses

in the Department of Psychiatry, supervised field observation in community and institutional programs, concluding with a thesis relative to a special project carried out by the candidate. Eight of the 20 months are in academic residence, divided into two 4-month periods; 4 months in academic residence, 12 months in a supervised administrative residency (or in a position already held by the candidate) during which a special project is carried out, and the final 4 months, again in academic residence. The course, as now set up, is designed to fit the individual's need for training, and to provide basic academic material that is lacking. By dividing the academic work in 2 sections, the candidate may take a leave of absence from his position, return to it for a year, and then complete the remainder of his academic residence.

There is a Curriculum Advisory Committee consisting of 10 experienced men and women who consult more formally with the faculty and are available to advise on the eligibility of candidates for admission. The United States Public Health Service has provided a few advanced traineeships for outstanding students.

The Menninger Foundation's School of Psychiatric Hospital Administration had its inception in an informal study group in administration set up at the request of third-year residents. Dr. R. C. Anderson, manager of Winter V.A. Hospital, described this experiment at The American Psychiatric Association's 6th Mental Hospital Institute in 1954, and noted, significantly, that the value of the training was so obvious that it was planned to give the undertaking more definite form(9).

The School as now constituted combines seminars in subjects related to mental hospital administration, with practical experience. Thus the work situation and the theoretical material can be correlated. Supplementing these 2 areas of training are university classes, staff and administrative conferences, elective seminars and the writing of several papers on selected problems of mental hospital administration. Work is undertaken on specific administration problems under the supervision of a certified mental hospital administrator(6).

At Topeka, the course in Psychiatric Hospital Administration is sponsored by the Menninger Foundation in cooperation with Topeka State Hospital, and Winter V.A. Hospital. This training is supplemented by field trips in Kansas to Larned State Hospital, Osawatomie State Hospital, Parsons State Training School, Winfield State Training School, and several hospitals in other states. Additional teaching in special areas of administration is provided by the personnel of the Goodyear Tire and Rubber Company, the Division of Institutional Management of the Kansas Board of Social Welfare, various divisions of the Kansas Department of Administration, the Kansas Legislative Research Council, the Kansas State Board of Health, and Stormont-Vail General Hospital(6).

Three general types of training are used: 1. didactic instruction; 2. a systematic rotation through major departments; and 3. staff conferences and other meetings; field trips, and written projects. The first consists of seminars on principles and techniques of organization and management, and on the problems of operating hospital departments; the second comprises rotation through the departments of each cooperating institution, to provide an opportunity to observe administrative practices in every important area of the hospital. Several Washburn University courses are included. The participation of a state, federal and private hospital enables students to observe the differences in operation of these 3 settings.

Admission to the School is limited to graduates of approved medical schools who are licensed physicians, who have adequate specialty training in psychiatry, have demonstrated an aptitude for administrative work, and an interest in hospital administration as a career(6). The Menninger Foundation provides a stipend of \$7,500 a year for a limited number of students. The first class, consisting of 2 psychiatrists, completed the course in June, 1956. They are now serving as superintendents of large mental hospitals.

I have described the plan of study at Columbia and the Menninger School in some detail, since they may well be the prototype for training in the specialty of administrative

psychiatry. It should be noted that the "trainee" is already a physician who has completed his training in psychiatry, and that the curriculum is designed specifically to fit him for a position as superintendent of a mental hospital.

The importance of the "atmosphere" of a mental hospital was noted earlier in this paper. This atmosphere is set, largely, by the superintendent. He should inspire respect and confidence in his staff and the lay public; he should have intellectual honesty, directness and decisiveness, and a breadth of view, and he should like what he is doing above all other activities (4, 8). This is a large order—and a challenging one. Comprehensive training coupled with a deep understanding of the significance of the administrative work will equip psychiatrists to meet this challenge and fill the need in this area of psychiatry.

RAPID TREATMENT OF THE PSYCHOTIC PATIENT INTEGRATING ELECTRONARCOSIS AND PSYCHOANALYTIC PSYCHOTHERAPY¹

ESTHER BOGEN-TIETZ, M. D., AND JO H. JORDAN²

THE PROBLEM

It is a common experience that recovery from a psychotic break is often only temporary or incomplete. We are convinced that many such unsatisfactory results can be prevented. The following case illustrates this point:

Martha, a 40-year-old housewife had been a perfectionistic, chronically helpful and intensely critical woman. During the fatal illness of her mother, Martha nursed her without rest. Returning to her husband and children following her mother's death, she could not eat or sleep and lost interest in everything. Following ECT over a period of several months, she returned home, apparently her "old self" again. Within a year, she relapsed into a serious depression and was again stabilized by ECT and supportive psychotherapy. A few months later, when her symptoms returned for the third time within 2 years, she was treated by a psychoanalyst; but he was unable to establish a workable contact. Becoming more remote and discouraged, Martha discontinued therapy; 2 months later she was hospitalized because of a psychotic depression. At this time she was started on a treatment program integrating intensive electronarcosis (EN) and dynamic psychotherapy. She returned to her husband and children and, with continued treatment, gradually gave up her obsessive-compulsive defenses. She has emerged a spontaneously warm, serene woman who no longer dominates everyone with helpfulness, and has shown no signs of depression in the 3 years since treatment began.

The basic personality of this patient was modified during the treatment and this may be the reason that she has remained well. Changes in the personality can occur only after the patient has given up unsatisfactory defenses and acquired more suitable ones. However, if we are to help a patient to change his defenses, he must be capable of contact. But the psychotic patient uses a withdrawal from reality contact as a major defense against anxiety-producing situations. The question is: How can one reach a person who habitually withdraws from contact?

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² From the department of psychiatry, College of Medical Evangelists, Los Angeles, Calif. Address: 544 Mariposa Ave., Los Angeles 5, Calif.

By prolonged and painstaking work, a few psychoanalysts have been able to reach the psychotic by utilizing the minimal reality contact of which he is still capable. The long time required for such treatment has two hazards for the patient:

1. Failure to establish a rapid return to reality estranges the patient's family, job and community relationships. This estrangement increases with time.

Ten years ago an executive giving a public address astonished a large audience by accusing the government of a fantastic plot. His family had observed his personality change over the preceding few weeks. He was hospitalized by a psychiatrist and treated with ECT 3 times a week for several weeks, followed by supportive psychotherapy. He quieted down without giving up his principle delusional ideas. He was unable to leave the sanitarium, much less resume his work. After 9 months of hospitalization, he was started on an intensive treatment program. At the end of 6 weeks, he was without gross symptoms. Nevertheless, it required 3 more weeks before we could persuade his wife to take him home. He had the greatest difficulty being reinstated in his job because, after such long hospitalization, his former associates feared and mistrusted him. During the patient's long absence his son had become delinquent and it was very difficult for the father to regain his son's confidence and help him.

In this case the patient's recovery was made especially difficult because the external contacts had deteriorated with time.

2. The longer the break with reality, the more restitution symptoms the patient will use to ward off anxiety.

Louise was an attractive 20-year-old college student from a cultured home. At college, away from home for the first time, she found it impossible to concentrate on her work, gave up social life and returned home in a panic. She became hostile and seclusive, and developed ideas that her parents wrote newspaper editorials about her and that there were spotlights focused on her. Almost at once she was taken to a psychoanalyst who treated her with daily psychotherapy for over 3 years. She was not able to resume her college work and led a bizarre life. She lived for a while in various sanitariums and sometimes in an apartment of her own accompanied by an elderly woman attendant; she was remote, unsocial, secretive and occasionally dangerous to herself and others. Finally, she had

to be committed because she was uncontrollable. After 6 weeks of hospitalization, during which she received 20 EN, she was started on active psychotherapy. One month later, she was able to leave the sanitarium and live with other recovering patients in an apartment, under supervision. Maintenance electronarcosis was continued along with psychotherapy. Three years after EN was begun, although she has attended college for 2 years and is becoming a spontaneous, active, charming person, she retains considerable anxiety regarding close relationships.

The slow recovery of Louise seems primarily attributable to the fixation of psychotic mechanisms since her break with reality was prolonged by palliative therapies. Of course, both of the deleterious effects of time are present in all cases.

Cases such as these have led us to the following convictions: (1) To insure lasting recovery from a psychosis, it is often necessary to change the prepsychotic personality. (2) The more rapidly contact with the patient can be established, the more rapidly can we restructure the personality. (3) EN can be used to obtain contact rapidly and to maintain it. (4) With adequate contact, psychoanalytic psychotherapy can be used to restructure the personality.

Below is a treatment program for the psychotic patient that utilizes simultaneous application of these two methods by individuals trained in both.

THE ROLE OF ELECTRONARCOSIS

Electronarcosis is a modified, electrically induced seizure followed by several minutes of subconvulsive electrical stimulation, sufficient to maintain bilateral flexor tone in the arms without interference with respiration. Since any state implying loss of control arouses great anxiety in a person whose ego is already seriously threatened, our technic of electronarcosis emphasizes the reassurance, comfort and safety of the patient. For example, special precaution against anxiety-producing conversation must be employed. Intravenous thiopental, to which has been added atropine and caffeine, is used to eliminate awareness of the placing of the electrodes and the insertion of tongue guards or the apprehension following muscle relaxants. Use of the glissando technic and of intravenous anectine permits control of the sei-

zure with a nearly complete elimination of muscular violence. Preoxygenation under positive pressure, routine insertion of an airway, and the use of carbogen (5% CO₂ in oxygen) following the initial grand mal seizure prevent anoxemia.

The patient is spoken to on awakening after EN to assure him that he is not alone, given a cup of coffee or other drink and allowed to rest as long as he wishes. This is the ideal time for establishing contact as described in detail below.

An essential feature of our use of EN is the spacing of the treatments. As soon as the patient is hospitalized and the diagnosis established, daily EN is begun and is continued until 10-12 treatments have been given. After that, the patient receives 3 treatments the third week, 2 the fourth week and then one a week until treatments can be spaced further apart and finally are no longer needed. In the subsequent stages of recovery, EN may be used to tide the patient over stressful periods.

With this spacing there occurs a predictable sequence of behavior. We consider the patient's progress as taking place through 5 stages. These are: (1) stabilization, (2) confusion, (3) reorientation, (4) rehabilitation, and (5) insight.

During the stage of stabilization, which occurs during the first week, the patient eats and sleeps better and appears his old self. He is polite and guarded, and his conflicts seem to be covered.

In the stage of confusion, in the second and third weeks, the patient unashamedly begins to show behavior which is characteristic of the first years of life. He may become extremely passive or aggressive, clinging, affectionate, untidy or exhibitionistic, often depending on nursing care for dressing and feeding.

During the fourth week the confusion clears and the patient reaches the stage of reorientation. He begins to make repetitive requests for orientation: Where am I? How did I get here? He appears demanding, self-centered, possessive, has a low frustration threshold, and reminds one of a preschool child.

During the stage of rehabilitation in the fifth and subsequent weeks, signs of self-

assertion appear and the patient's capacity for simple enjoyment is markedly increased. Although dependency needs continue, as evidenced by moodiness and rejection of responsibility, the patient shows increasing ability for reality contact and an eagerness for new experiences.

In the stage of insight the patient behaves much like a neurotic person.

This unfolding of successive phases during EN treatment facilitates the concomitant use of dynamic psychotherapy.

THE ROLE OF PSYCHOTHERAPY

Psychotherapy is varied according to the patient's progress. In the stage of stabilization only friendly attention is offered. Attempts to uncover conflicts are usually futile and may reactivate psychotic symptoms.

The treatment of the patient in the period of confusion is an essential aspect of our method. This brief, undefensive state is utilized to meet the emerging infantile needs of the patient with maternal care. Regressed behavior and speech, messing with food or incontinence are not rejected or criticized. All persons connected with the patient's care accept his behavior without undue emotion, the way a sensible mother takes care of an infant. Visitors are not encouraged during this time: we aim at a complete relaxation of standards conforming to the requirements of adult social living. During this stage the therapeutically correct response of all concerned with the treatment is more important than the patient's contact with one specific therapist.

The state of confusion is important in two ways: the uninhibited patient conveys to the observing therapist drives otherwise masked and distorted by habitual defenses. This facilitates rapid understanding of dynamics which will prove time-saving in later psychotherapy. Also, during this time of confusion, we have an opportunity to change the patient's way of responding to human contact and thus to reality.

As the patient wakes up from EN, his recognition of the outside world is slowed down. The recovery room in which he awakens offers a peaceful, reassuring atmosphere. We use a procedure symbolic of infant feeding to observe the patient's re-

action to external stimuli and to establish contact. The most accessible state is immediately following an EN, during the second and third weeks. The physician or assistant carrying out this procedure in the first awakening moments should be capable of establishing an atmosphere of maternal warmth, tenderness and total acceptance. Standing close to the patient, the therapist presents a moistened, rope-handled lollipop to his lips. The patient may make sucking movements, opening his mouth, or clenching his teeth to prevent the candy from entering. He may accept the candy and bite it fiercely; he may spit it out or actively prevent its removal. The therapist does not interfere but, guided by the patient's response, continues to offer the stimulus with encouraging words such as "It is good," "You can take it," "I'll give it back to you." And with this the therapist attentively follows the patient's eyes, his every move and change of expression.

When the patient seeks the therapist's eyes with a smile, we conclude that he has associated pleasure with the mother surrogate. This conclusion is confirmed by subsequent efforts to touch the therapist. This acceptance of maternal care is the beginning of anxiety-free contact with the outer world. When the patient wakes up fully, he may return to his remote or hostile attitude. However, repetition of these contacts over a period of about 2 weeks establishes a positive relationship between the patient and other persons. This becomes the basis for communication in the succeeding period of reorientation.

Once the patient has begun to accept help and satisfaction from others, we augment his receptiveness to external sources of pleasure, while avoiding overstimulation. The therapist does not confront the patient with difficult reality problems during reorientation. Like the preschool child, he must not be overtaxed. The therapist gives continuous encouragement, sharing walks, treats, games and small errands. Before the patient leaves the hospital, the human contact which we offer will have become indispensable.

Contact is established with close relatives of the patient, individually or in a group, to help them acquire understanding and to prepare them for the patient's homecoming.

Where the environment is too destructive, the patient is helped to accept a new environment.

When he returns to the community, the integrated treatment program continues on an ambulatory basis. The rehabilitation period is often used by the therapist to guide the patient toward realistic changes in his life situation which will prevent a return to passive adaptation. We do not hesitate to become active when necessary: we may aid the patient to find a job and living quarters; we may guide him to educational and social opportunities, or even assist in managing a budget. Being genuinely helpful without magic or omnipotence, the therapist becomes an ally.

With support, the patient learns to meet reality with less anxiety. As he evidences further ability for reality testing, he receives some expression of the therapist's appreciation of his progress. We make use of any common ground to break through the patient's former isolation. Empathy and active advice, however, do not necessitate entering into the patient's problems; after all, our ultimate goal is to render the patient independent. To this end we encourage efforts at selfassertion and critical judgment, although it may be aimed at the therapist. In therapy the patient often realizes for the first time that disagreeing does not destroy an established relationship. Once convinced of this, he can permit himself to differ from important people and from the rules of his early training, instead of retreating into hostile remoteness.

A valuable means for promoting ego strength is identification with a group, either in an activity program or in group psychotherapy. As soon as the patient begins an active search for companionship and gratification, his choice and judgment are watched and at times supervised to exclude real danger.

Progress and growth during rehabilitation are rarely smooth or continuous and are met with flexibility in techniques. Above all, the therapist with his knowledge of the usefulness of EN can recognize the need for maintenance treatments to assure uninterrupted reality contact without excessive anxiety or acting-out.

Acceptance in this re-educational period of psychotherapy is tempered with firmness in which the therapist's integrity holds up in spite of testing pressures from the patient. Pressures stemming from emerging impulses are dealt with by interpretation. Once the transference has been firmly established, the patient is helped to become more aware of his emotions. His clinging to old ways of reacting is interpreted, while therapy encourages him to recognize and seek satisfaction for his present day needs. This marks the beginning of insight psychotherapy.

Insight psychotherapy with the recovering psychotic patient differs somewhat from that used with the neurotic patient. The therapist is not simply a passive reflector and objective interpreter of the patient's past and present conflicts; but remains ready to intervene actively to prevent too high a level of anxiety by shifting as necessary from passivity to active alliance with the patient.

SUMMARY

The psychotic patient, no matter what his underlying character structure may be, reacts against deprivation with the defense of a break with reality. Intensive EN quickly produces a state in which gratification of infantile needs becomes the basis for reality contact. While reality contact is sustained with maintenance EN, re-education leads to a secure basis for restructuring psychotherapy. This, in turn, makes the defensive break with reality unnecessary.

DISCUSSION

DR. BERNARD C. GLUECK, JR., M. D. (Minneapolis, Minn.).—The technique described by Dr. Bogen-Tietz, using daily electronarcosis treatments, appears to produce changes in the psychological organization of the patient and in his physiological responses similar to those observed in patients treated with the technique first described by Milligan in 1946, which involves the use of 3 electroconvulsive treatments per day on a daily basis. The stages of change described by Dr. Tietz correspond remarkably with those observed using 3 convulsions a day rather than 1 convulsion followed by some minutes of electrostimulation. It is interesting to speculate upon the changes in the brain which lie behind the psychological and physiological changes observed in the patient.

We have been concerned with investigating this problem during the past year, and at the present time are looking into the general thesis that the electric current and the convulsive seizure produce a marked vasoconstriction of all of the blood vessels supplying the brain. In the ordinary convulsive treatment this lasts from 40 seconds to perhaps as much as 3 or 4 minutes, usually followed by a marked vasodilation. Perhaps with the convulsive seizure followed by electrostimulation, the vasoconstriction persists during the entire period of the stimulation, resulting in a much longer period of diminished blood supply to the brain than with the usual electroconvulsive seizure. We are working on the premise that this vasoconstriction produces some type of deprivation to the cortical cells which is responsible for a shift in metabolism of the brain tissues. That this may be related to the rather marked physiologic, as well as psychologic changes in the patient, remains to be demonstrated, but appears to be a promising line of investigation.

However these changes may be produced, the very rapid shift from a state of chronic tension and anxiety, with its various physiologic and psychological manifestations, to a state of relative homeostasis marked by freedom from anxiety, and a shift in the physiologic state to a more nearly normal situation, is extremely impressive. It leads one to the conclusion, which may perhaps be wishful thinking, that we are able to reverse quite rapidly, through the use of these techniques, the destructive effects of the chronic anxiety and tension

that appear to be part of the psychotic process. The memory impairment described by Dr. Bogen-Tietz, which in the 3-times-a-day convulsion technique is a complete amnesia lasting for 7 to 14 days, may be involved in the therapeutic response. It does not appear, however, to be the destructive, interfering, to-be-avoided-at-all-costs, kind of result of the electric stimulation of the brain that has been ascribed by many clinicians to these techniques. The memory loss has also led to serious criticism of any electrostimulating procedures, since this was interpreted as representing serious brain damage, and also was supposed to produce marked interference with any kind of psychotherapy following treatment. Dr. Bogen-Tietz has described a marked facilitation of psychotherapy following this type of treatment. Our own experience confirms this finding. Not only is the increased accessibility described by Dr. Bogen-Tietz an important part of the pattern, but we have found a consistent improvement in the recovery of early memories that were previously repressed. This is one of the results of treatment most commonly referred to by our patients. They contrast the sharp improvement in the recovery of remote events with the difficulty in recent memory. It has resulted in our being able to construct far more accurate psychodynamic formulations in terms of early life experiences, and has helped the patient to integrate the early traumatic experiences with the behavior patterns of the adult years.

There appears to be one difference in the results of the electronarcosis and the standard electroconvulsive method in that we find a persistent amnesia for the events immediately preceding the treatment, with the retrograde period being determined apparently by the duration of the acute psychotic process. This may be anything from several weeks to as long as 1 to 2 years.

I would like to re-emphasize Dr. Bogen-Tietz' contention that the rapid interruption of the psychotic process is of tremendous therapeutic importance, both from the standpoint of relieving symptoms at the earliest possible moment in order to facilitate contact with the patient, and also to prevent the patient from using over and over again the processes of miscarried repair that are the hallmark of the psychotic break and the failure of reality adaptation. I believe that Dr. Bogen-Tietz has made a very important contribution to our treatment of the psychotic patient, and am hopeful that this sort of experimentation with variations in the application of electric current to the brain will continue, since we have, as yet, no uniformly satisfactory approach to the problems presented by the many varieties of psychotic disturbance that we are daily called upon to treat.

CLINICAL NOTES

OBSERVATIONS UPON THE THERAPEUTIC USE OF BENACTYZINE SUAVETIL¹

VERNON KINROSS-WRIGHT, M.D., AND JOHN H. MOYER, M.D.²

Benactyzine is an anti-cholinergic drug first made in 1936 by the Ciba Laboratories, with the following formula:

Clinical results achieved by Jacobsen, Munkvad and others in many hundreds of patients in Denmark indicate 50-80% im-

Benzilic Acid Diethylaminoethyl Ester HCl

Jacobsen and his co-workers in Denmark studied Benactyzine and a number of related compounds on the assumption that an excess of acetylcholine in the nervous system might underlie certain types of emotional illnesses. Pharmacologically, the drug resembles atropine though less potent in its peripheral parasympatholytic effects. There is but little effect upon the blood pressure and little or no sedation. It has pronounced local anesthetic activity. Central effects of the compound have been carefully explored by Jacobsen in a series of animal and human experiments. Utilizing a modification of Masserman's technique, he found that the drug would abolish the characteristic behavior in a conflict situation. Signs of stress in animals conditioned to an escape response were minimized; simultaneously their responses became faster and better coordinated.

In man, Benactyzine (in larger than therapeutic doses), according to Jacobsen, produces dizziness, relaxation of the musculature, thought blocking with reduction in spontaneous associations; and some tendency to lose the train of thought, complete or partial suppression of the alpha rhythm in the electroencephalogram, and a reduction in autonomic response to emotional stress.

Improvement in neurotic patients. Anxiety reactions and compulsive states were most influenced while there was little influence upon schizophrenic, hysterical or depressive conditions. Side-effects were transient and included peripheral atropine-like effects and occasional unmotivated mirth. Munkvad used as much as 90 mg. daily in psychotics without improvement. The average dose, however, for neurotic patients was 3-10 mg. daily.

Substantially similar results have been reported by Davies and others from England. These British writers have been more concerned though about the bad effects of the drug upon attention, thinking and judgement.

We were impressed by the Danish reports and decided to give Benactyzine a clinical trial early in 1956.³ Seventeen normal volunteers were given 1-5 mg. of the drug in a single dose. With the larger dose, heaviness of the limbs, dilatation of the pupils, euphoria and some distortions in the perception of the passage of time were noted. Two of the subjects noted difficulty in organizing their thoughts and keeping track of what they were saying. Ten of the subjects (on 1 mg. dosage) were not able to distinguish the drug from an identical placebo taken in the same experiment.

¹ Benactyzine is sold under the name of Suavetil in Denmark and England.

² From the Departments of Psychiatry and Pharmacology, Baylor University College of Medicine, Houston, Tex.

³ Benactyzine was kindly supplied by Smith, Kline & French Laboratories, and Lloyd, Dabney & Westerfield.

Over 70 patients have received Benactyzine though only the first 42 are considered in this report. The patients were all treated in the outpatient clinic and included representatives of the various types of psychoneuroses as well as a few depressions and two schizophrenics. Dosages varied from 3-16 mg. a day in divided doses for periods up to 12 weeks. No attempt was made to establish controls in this preliminary study and some of the patients were receiving concurrent psychotherapy. A number, however, were given identical placebos without their knowledge for varying periods during treatment. In most cases the patient could readily distinguish these from the active drug largely because of lack of side-effects. However, some claimed satisfactory relief from placebo. Of our patients about one-third were greatly improved by both objective and subjective criteria; one-third obtained some benefit and the remainder were unchanged or worse.

Side-effects were infrequent with doses of less than 4 mg. daily. With 4-8 mg. atropine-like effects of dryness of mouth, pupillary dilation, slight palpitations and also occasional difficulty in concentration were noted by a number of patients. In doses above 8 mg. daily these symptoms were noted by one-half of the patients with the addition in some of nausea, anorexia, and constipation. Those taking 12 mg. daily or more were often considerably bothered by heaviness of the limbs, feelings of mental confusion (subjective), emotional lability and feelings of unreality and drowsiness. Dizziness and

ataxia were found in some. One patient developed a maculo-papular skin rash. The high incidence of side-effects, particularly the impairment of thinking, caused many patients on the higher dosage to request discontinuance of Benactyzine.

A good clinical response was associated with a calming effect without undue sedation. This was especially noteworthy in the face of formerly stressful emotional situations. We did not observe major changes in neurotic patterns of thinking or behavior. Most were less bothered by the autonomic concomitants of anxiety than formerly, except where side-effects coincided with these. A small number of patients reported their anxiety aggravated by Benactyzine, apparently the result of feelings of depersonalization and lightheadedness.

Comments: Benactyzine produces some interesting and sometimes therapeutically useful effects upon emotionally disturbed patients. Its greatest value appears to lie in the reduction of emotional reactivity to stress. In our hands the drug has not achieved the highly favorable results reported in the Danish and British literature. The incidence of uncomfortable side-effects in our patients has been considerable. It is almost superfluous to comment that the evaluation of any drug offered for the treatment of psychoneuroses requires precise and controlled research design. We report these preliminary observations because of the considerable interest that this compound has aroused in the United States.

THE DUAL ACTION OF THE TRANQUILIZERS

JOSEPH A. BARSA, M.D.¹

A tranquilizer, in contrast to the "older" sedatives like the barbiturates, is defined as a drug which calms the emotions without affecting mental acuity. Truitt has classified the drugs chemically into 4 main groups, as follows: 1. Rauwolfia alkaloids, of which reserpine is the most important; 2. Phenothiazine derivatives, such as chlorpromazine (Thorazine), promazine (Sparine), promethazine (Phenergan), mapazine (Pacatal), prochlorperazine (Compazine); 3. Pro-

panediol dicarbamate or meproamate (Miltown, Equanil); 4. Diphenyl methanes, of which the most important are azacyclonol (Frenquel), benactyzine (Suavetil), hydroxyzine (Atarax).

It is used to be thought that the tranquilizing effect or calming effect was the principle therapeutic action of these drugs, and that it was this which operated both in allaying the anxiety of the neurotic and in allowing the schizophrenic to shed his delusions and hal-

¹ Rockland State Hospital, Orangeburg, N. Y.

lucinations. In other words, if the anxiety of the schizophrenic were truly relieved without reducing mental acuity, there would be no further need for delusions and hallucinations which have been considered by some as defenses against anxiety.

However, judging from my own clinical experience I believe that there are two separate and distinct effects of these tranquilizers—a tranquilizing effect which calms the patient, and, (for want of a better term) an anti-psychotic effect which combats the delusions and hallucinations of the schizophrenic. These are separate and distinct effects, for one can occur without the other. For example, I have on occasion treated rapidly an actively psychotic schizophrenic with such large doses of reserpine that the patient has become first lethargic, later mentally confused, and finally even semi-comatose. I have then withdrawn the drug, and, on regaining his alertness, the patient has been in a remission of his psychosis, this remission remaining for many months. Certainly the remission was not produced by a tranquilizing effect as I have defined it. Furthermore, in treating a schizophrenic with reserpine or one of the phenothiazines, we sometimes leave him with considerable (at times increased) tension and anxiety, even though his delusions and hallucinations may have disappeared. On the other hand, it is possible to obtain what is apparently a truly tranquil-

izing effect without eliminating the delusions and hallucinations. This is most common with meprobamate which is one of our best tranquilizers, but which has a negligible anti-psychotic effect. Thus, the tranquilizing and anti-psychotic effects in these drugs can be considered separately and evaluated separately. We can, therefore, list the 4 groups of tranquilizers in the order of their tranquilizing effectiveness as follows: meprobamate, phenothiazines, Rauwolfia, and diphenyl methanes. But in the order of their anti-psychotic effectiveness they are: phenothiazines, Rauwolfia, meprobamate and diphenyl methanes. It should be noted that the above listings are based on the average response of patients, and it does not preclude individual exceptions.

Does all of this mean that the tranquilizers act on one cerebral center for their tranquilizing effect and on another for their anti-psychotic effect? Perhaps. Further research must be done in this area.

Does this also mean that the tranquilizing drugs in their anti-psychotic effect strengthen the patient's ego structure? Definitely not. When a schizophrenic is in remission as a result of drug therapy he is just as liable to plunge again into psychosis unless the ego is protected by a maintenance tranquilizing effect of the drugs, or, better still, unless the character structure is changed and strengthened by intensive psychotherapy.

CORRESPONDENCE

ELECTROSHOCK THERAPY

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: We wish to confirm the advantages of the method of treatment described by D. J. Impastato in The American Journal of Psychiatry, 113: 461, 1956.

Impastato does not use barbiturates before electro-convulsive treatment, but only 10 mgms. of succinylcholine. He follows it 10 seconds later with a *petit mal* electro-convulsive stimulation and 20 seconds later with the usual *grand mal* stimulation. He has used it till now in 100 cases.

This method, first introduced by one of us 2 years ago when working with Dr. S. V. Marshall as anaesthetist, has been used by us for all patients needing relaxants over the past 18 months. We have successfully used it till now in about 3500 treatments and never once used pentothal.

Our method only slightly varies from the method described. We are using the Minecta Electrotherapy Unit with Electronic Timing and automatic glissando. The voltage ranges from 80-140V, the timing from 0.5-2 seconds, the muscle relaxant used is Brevidil E.

Patients are given sodium amytal gr. 3 to 6 an hour before treatment in order to decrease the apprehension which psychiatric patients feel for any strange procedures. The sub-convulsive stimulation (80-90V 1 sec) if given at the correct time and repeated if necessary, causes complete amnesia for any

unpleasant accompaniments of the relaxant. We have found that it is wise to give the first subconvulsive stimulus 10 seconds after the injection of the relaxant and to repeat the stimulus if the onset of relaxation appears to be at all delayed. Inhalation of oxygen by the patient during injection and up to the time of the first stimulus lessens the danger of any unpleasant preliminary sensation. Oxygen is also administered under pressure after the cessation of the "convulsion" until respiration is fully established. We consider this essential in order to avoid any anoxaemia, and clinical impression is that this avoids confusion especially in elderly patients.

In some cases inflation with oxygen before treatment is all that is needed to eliminate the subjective feeling of oppression or suffocation, and no subconvulsive stimulation is necessary.

This method successfully eliminates the necessity for intravenous barbiturates, not only shortening and simplifying the procedure, but also eliminating the complications which have occasionally followed the injection of pentothal.

We are therefore in full agreement with Impastato's conclusions and advocate elimination of pentothal from electro-convulsive therapy.

A. T. EDWARDS, M. B. B. S. (Syd.),
I. A. LISTWAN, M. B. B. S. (Syd.),
Sydney, Australia.

REPLY TO THE FOREGOING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: I was very glad to be informed that Drs. Edwards and Listwan have used this method of treatment in over 350 patients successfully and that they feel as I do that it is best not to administer intravenous barbiturates to patients undergoing electro-convul-

sive therapy. It is still my opinion that the technic described is the safest, simplest and best one so far devised for electroshock therapy.

The only complication of the treatment is that a fairly good number of patients develop some anxiety. Although the incidence of anxiety is not greater than that developed by

patients receiving unmodified electro-convulsive treatment, it is still a problem and should be avoided as much as possible. We are presently studying this problem. I was, therefore, very glad to learn that Drs. Edwards and Listwan, in order to diminish the anxiety, use sodium amytal by mouth one hour before treatment and preoxygenate the patients just prior to the treatment. I have already tried

the suggestion of preoxygenating the patients before treatment and so far find it very useful.

Drs. Edwards and Listwan should be congratulated, *inter alia*, for their modifications which apparently diminish the anxiety and enhance the usefulness of the technic.

DAVID J. IMPASTATO, M. D.,
New York City

COMMENT ON LETTER FROM DRs. EDWARDS AND LISTWAN

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: With my approval Drs. Edwards and Listwan have mentioned my name in their letter regarding the method described by Dr. Impastato, because as anesthesiologist I was associated with Dr. Edwards in his earlier trials of this new method, which he considers to be superior to the usual sequence of thiopental and succinylcholine (SCC) for the purpose under consideration. May I hasten to state that, after an experience of some 15,000 applications of the latter combination during the past 7 years, I must disagree entirely with the conclusions reached by Drs. Edwards and Listwan in this connexion. So too, apparently, with Dr. Impastato.

In my opinion it is nothing short of miraculous if Dr. Impastato was able to get adequate relaxation with only 10 mgms., or less, of SCC acting over a period totalling 30 seconds. Employing the usual technic my present conclusions are that SCC requirements generally range between 15 and 65 mgms., and that such dosages must be allowed from 60 to 90 seconds to act fully before the *grand mal* stimulation is given, depending on the build, health, age, etc., of the patients concerned. Only thus may truly efficient modification of the convulsion be obtained in all cases, and yet ensure the restoration of normal breathing almost immediately afterwards. Of course artificial respiration with oxygen by means of a Waters' 'bag-and-mask' outfit must be practised both before and after the *'grand mal'* EST stimulation under these circumstances, especially in aged and cachectic subjects. Some psychiatrists affect to despise the use of oxygen in

this manner, and claim that the brief period of apnea following their particular mode of EST is of no consequence. Any competent anesthesiologist, and even anesthetist, knows that any hypoxia, no matter how brief, can damage the ageing brain or heart, sometimes irreparably. Much later confusion and disability, and even untimely death, can be traced back to such neglect to provide adequate lung ventilation and tissue oxygenation during any period of physical stress or impaired respiration. Obviously the efficient giving of oxygen should be an invariable routine in all applications of EST, no matter how healthy the patients might appear to be.

To avoid thiopental on the rather specious grounds that this omission obviates danger, and to give instead a *'petit mal'* EST stimulation only 10 seconds after the relaxing agent, followed in a further 20 seconds by a *grand mal* stimulus, must deprive the procedure of its chief object of preventing traumatic complications. It seems to me that this egregious device has only two advantages; first, cheapness, and second, that by 'going through the motions' of modifying the therapy the operator is merely protecting himself against future legal hazards. To argue that the avoidance of thiopental and the services of an anesthetist reduces the dangers of the treatment is indeed a telling commentary on the general state of anesthesia in the United States of America. It also reflects gravely on the physiological knowledge of the psychiatrists, of whatever country.

To my mind, that of a mere anesthesiologist, the 'no-thiopental' method is based on the false premiss that the preliminary use of thiopental is always dangerous, whereas this is not so when its application is under rea-

sonably expert control. Further the restriction of SCC to virtually ineffectual dosages might also be thought to widen the safety-margin. May I submit that both of these contentions are fallacious, the prevalence of which fallacies indeed do make some psychiatrists chary about using the ordinary sequence. With proper facilities and in competent hands, however, the standard method is eminently satisfactory to both operator and subject alike, while its safety for all cases under similar conditions is quite unquestionable.

As for the 'no-thiopental' device, it is inelegant; it does not effectually suppress the patients' apprehensions, and it favours undue restlessness afterwards. Even if it might

permit a more speedy restoration of animation, this is not infrequently of delirious character. The thiopental/SCC sequence, well-conducted, is far superior in almost all respects, and there is practically no reason why any intelligent psychiatrist, who wants to save his patient the expense of an anaesthetist, should not be able to learn and conduct safely this valuable technic either for himself or for one of his colleagues.

As one who prefers simplicity whenever possible I must, with some regret, oppose the advocacy of Drs. Edwards and Listwan for the elimination of thiopental from electroshock therapy.

S. V. MARSHALL, M. B., Ch. M.,
Sydney, Australia.

HIGH COST OF ANALYTIC TRAINING

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: The revelations of Potter, Klein and Goodenough (Am. J. Psychiat., 113:11, May 1957) raise interesting questions regarding the proportion of a professional specialist's life that should be spent in formal education. For those who harken to the "Sound of a Distant Dream," pity would be insulting, but the plight of their families cannot fail to arouse sympathy.

Possibly psychoanalytic training could be budgeted for in retirement insurance pro-

grammes. At all events, the whole question of how far the will o' the wisp of complete self knowledge should be pursued bears energetic ventilation among psychiatric educators and students.

Those of us who were able to take at least our residency training in institutes where we could study our patients and books with reasonable leisure and security have a great deal to be thankful for.

L. R. MUNDY, M. D.,
Hartford, Conn.

VERITAS

The *Moone* hath her *spots*, and the greatest men have their *failings*. No man is free from error in this life. Truth could never yet be *monopolized*; the great merchants of spiritual *Babylon* have not ingrossed it to themselves, nor was it ever tyed to the Popes *Keyes*, for all their brags: The God of truth send us a time wherein mercy and truth may meet together, righteousness and peace may kisse each other. *Amen*.

Medici* (1645)

COMMENT

THE CHICAGO MEETING

The 113th annual meeting of The American Psychiatric Association was held in Chicago, Illinois, at the Morrison Hotel, May 13 through 17, 1957. All sessions took place at the Morrison Hotel excepting some of the round table conferences that were assigned to the Sherman Hotel. The official opening was held in the Terrace Casino on Monday, May 13, and was called to order by the President, Dr. Francis J. Braceland, at 9:15 a.m. The Invocation was given by Rev. W. J. Devlin, and The Association was welcomed to Chicago by Dr. Roscoe Miller, Dean of the School of Medicine of Northwestern University. Dr. Braceland introduced President-elect Dr. Harry C. Solomon, who responded briefly thanking the membership for bestowing this great honor upon him. This was followed by the tenth annual report of the Medical Director, Dr. Daniel Blain, in which he reviewed the highly important activities of the central office during the past year. Dr. Matthew Ross, Speaker of the Assembly of District Branches, reported on the achievements and progress of this body which was organized in 1953. The Chairman of the Committee on Arrangements, Dr. Hugh T. Carmichael, presented the report of the exceptionally well-planned and successful organization of the various functions of the annual meeting. He emphasized the fact that the entire membership of the Committee contributed materially to the planning and that an outstandingly attractive program for entertainment for the ladies was organized by the Ladies Committee, with Mrs. D. Louis Steinberg as Chairman. Dr. Titus H. Harris, Chairman of the Program Committee, reported on the composition of the program, which consisted of 132 scientific papers and 30 round table conferences. The Secretary reported the official membership statistics stating that as of March 31, 1957 the total was 9,205. The Treasurer presented his report on the present financial status of the Association. The Hoiheimer prize was presented to Dr. Christoph M. Heinicke of

Portland, Oregon, for research done in London, England and reported in the monograph, "Effects of Separating Two-year Old Children from Their Parents: A Comparative Study." The Isaac Ray award was presented to Dr. Manfred S. Guttmacher of Baltimore, for his outstanding contribution to the better understanding between psychiatry and jurisprudence. The Mental Hospital Achievement silver plaque awards were then announced by Dr. Daniel Blain and will be presented this Fall to the Saskatchewan Mental Hospital, Weyburn, Sask., Canada, and to the Receiving Hospital, Detroit, Michigan. Honorable Mentions were given to the Northern State Hospital, Cedrowoolley, Washington, and the Madison State Hospital, Madison, Ind. Election of new members and Fellows took place at this session and this made it possible to hold the convocation for newly elected Fellows at a highly impressive and dignified session on Tuesday morning. The number of newly admitted members was 667, broken down as follows: 341 associate members, 313 members, 2 reinstatements, 11 corresponding Fellows.

The highlight of this opening session was the address by the President. It was a most thoughtful, comprehensive and inspiring message in which Dr. Braceland reviewed the present status of psychiatric practice and research and the guiding principles of continuing the progress of the Association. The President-elect, Dr. Harry C. Solomon, responded warmly and appreciatively to the presidential address. The Benediction was given by Reverend Donald Cox, Chaplain of Kankakee State Hospital.

The next business session for the membership was called to order by the President on Tuesday morning, May 14. The Board of Tellers reported the results of the ballots both for the election of officers and the vote on the amendments to the Constitution and By-laws. The total number of ballots mailed was 7,200; 4,398 ballots were returned, 28 of which were invalid. The officers elected for 1957-1958 were as follows: Dr. Francis J.

Gerty, President-elect; Dr. William Malamud, Secretary; Dr. Jack R. Ewalt, Treasurer; incoming councillors: Dr. C. H. Hardin Branch, Dr. Addison M. Duval, and Dr. Jacques Gottlieb. The proposed amendment to the Constitution to provide the establishment of two newly elected officers to be known as Vice-presidents, drew a vote of 3,755 in favor, 146 opposed, and 48 invalid ballots. The result of the vote to amend the By-laws was 3,752 in favor, 146 opposed, and 48 invalid ballots. Reports were then presented by the Coordinating Committee Chairmen to review the activities and plans for their respective Standing Committees. Dr. Wilfred Bloomberg reported for the Committees on Professional Standards, Dr. Frank J. Curran for the Committees on Technical Aspects of Psychiatry, and Dr. William C. Menninger reported for the Committees on Community Aspects of Psychiatry. Following the business session and after a brief recess, the second annual convocation ceremony honoring newly elected Fellows was held in the Terrace Casino, at which Dr. Solomon presented a reading on "The Objectives of The American Psychiatric Association" and Dr. Francis J. Gerty, the incoming President-elect, spoke on "Fellowship in the American Psychiatric Association." Dr. Braceland welcomed the incoming Fellows and Rev. Edward P. Dickson gave the Benediction.

The program was distinguished in several respects. The Association commemorated at this meeting the 100th anniversary of the birth of Professor Eugen Bleuler who has made such signal contributions to psychiatry. The commemorative exercises were highlighted by the Fellowship Lecture by Dr. Gregory Zilboorg entitled "Eugen Bleuler and Present Day Psychiatry." Bleuler's contribution was discussed in terms of its relationship to the contributions of his two great contemporaries, Kraepelin and Freud. Dr. E. Eduardo Krapf gave a scholarly response to Dr. Zilboorg's provocative address.

The scientific program was organized most effectively by Dr. Titus H. Harris and his committee, and, in keeping with the present trend in psychiatry, contained a large number of contributions to research, ranging all the way from biochemistry and pharmacody-

namics to psychological, psychopathological and social studies. Notable on this program was the first Adolf Meyer Research Lecture which was given by Dr. Stig Akerfeldt of the Nobel Institute, Stockholm, Sweden, on his recent work in the field of "Serological Reactions of Psychiatric Patients to Dimethyl penyline diamine." This was organized by the Program Committee in collaboration with the Committee on Research, and a number of scientists participated in reporting their work in relationship to the results of Dr. Akerfeldt's investigations.

The next business session was held on Wednesday morning, May 15, in the Terrace Casino. The Secretary reported the actions of the Council during the past year which were duly approved by the membership upon motion from the floor. The establishment of a number of new district branches was approved by the membership. Another feature of this program was the presentation of certificates to the retiring councillors and committee chairmen of the Association.

The annual dinner was held also in the Terrace Casino on Wednesday evening, May 15, and was well attended. The highlight of the evening was the presentation of a commemorative framed certificate and silver bowl to Mr. Austin M. Davies, Ph. B. by Dr. Clarence B. Farrar, Editor of the AMERICAN JOURNAL OF PSYCHIATRY, on the occasion of Mr. Davies's twenty-fifth year of dedicated service to the American Psychiatric Association in the capacity of Executive Assistant and to the AMERICAN JOURNAL OF PSYCHIATRY as Business Manager. The presentation of the past-president's medal to Dr. Francis J. Braceland was made by Dr. Kenneth E. Appel.

The final business session was held on Friday morning, May 17, with Dr. Braceland presiding. Dr. Braceland presented the gavel to Dr. Solomon signifying his assumption of the presidency, and the 113th annual meeting was officially closed at 5:00 p.m. on May 17.

The meeting in general stood out as one of the finest in the history of the Association and was eminently successful both scientifically and socially. The total attendance was as follows: members 1,924, non-members 953, complimentary (undergraduate and graduate students) 137, guests 523, and ex-

hibitors 199, a total of 3,736. The success of the meeting was largely due to the great leadership and wise guidance of Dr. Francis J. Braceland, the retiring president, and the harmonious cooperation of the entire membership, officers and committees. Special recognition and thanks should go to those who have helped in making this success pos-

sible, more particularly to Mr. Austin M. Davies, the Executive Assistant, Dr. Blain and Messrs. Robinson and Turgeon of the central office, and members of the staff of both offices as well as the Committees on Arrangements and Program.

WILLIAM MALAMUD, M. D.,
Secretary.

MIND MOLDS

From what I have said, it is clear that I was in the intellectually enviable position of being able to approach these [religious] problems without that conditioning in youth which, for the large mass of Christians, stigmatizes doubts of creed or critical appraisal of doctrine as reprehensible or even sinful; and which automatically inhibits later contemplation except from theologically fixed premises. My mind was not, in the liquid state of childhood, poured into a mold and allowed to harden into one the other of the ingots of Christian denomination which, whatever their minor differences of pattern, all hold through life, unmalleable in the fires of reason, the basic form of unquestioning faith.

—HANS ZINSSER
(The Biography of R. S.)

CREEDS

On every hand, in individual as well as in national life, numberless facts proclaim that human nature is better adapted to the circumstances of existence than to require, under threat of dissolution, the solution of ultimate problems. The revelations that come to man disclose ever proximate goals, and each new step means a new revelation. . . . To have observed that human society generates moral ideals together with impulses and desires to realize them, is, whatever our theories about them, sufficient for practical life. To have gained that knowledge is to have secured ground unshakable by any philosophy. . . .

He has a sufficient living creed who can affirm that moral forces actually come into existence in human society, and that its welfare and the individual's self-approval and self-respect are, as a matter of fact, indissolubly bound with the fulfillment of the moral demands.

—JAMES H. LEUBA,
The Belief in God and Immortality

NEWS AND NOTES

NATIONAL COMMITTEE AGAINST MENTAL ILLNESS, INC., WASHINGTON, D. C. (EXECUTIVE DIRECTOR, MIKE GORMAN).—This Committee has prepared a brochure (45 pp.) containing a great variety of statistical facts regarding mental illness in the United States. Date of compilation: January 1957.

The facts herein are drawn from many reliable sources—national and state agencies, and special surveys and reports. The Biometric Branch of the National Institute of Mental Health of the U. S. Public Health Service cooperated with the Committee in preparing the data here presented. Both clinical and economic aspects of the problem are set forth in figures, also the degrees of efficiency of the various state services, and amounts spent or required for new hospital construction, and personnel increases to care for urgent needs. There is a summary, broken down, of the overall direct cost of mental illness in the country today. This annual cost is estimated at approximately \$4,172,124,955.

There are about 586 mental hospitals in the United States. The average bed shortage is 44%. Of 124 hospitals inspected by the Committee appointed for that purpose by THE AMERICAN PSYCHIATRIC ASSOCIATION, 8 received approval, 31 conditional approval, 85 were below minimum standards.

Approximately \$27,353,000 is being spent on research by state, federal, and other agencies. The results are tabulated by states. Encouraging results of the newer drug treatment are shown in a lowering quite generally of the annual hospital census.

The address of the National Committee Against Mental Illness, Inc. is 1129 Vermont Ave., N. W., Washington 5, D. C.

DEVEREUX DINNER AND PROGRAM.—The 16th annual dinner generously given by The Devereux Foundation in connection with the annual meeting of THE AMERICAN PSYCHIATRIC ASSOCIATION was held in the Grand Ballroom of the LaSalle Hotel, Chicago,

Monday evening, May 13, 1957. Nearly 500 guests were present.

Following the dinner, Dr. Roy Grinker, moderator, introduced Dr. Edward W. Bortz, chief of the medical service, Lankenau Hospital, Philadelphia, and past president of The American Medical Association, who spoke on "Growth and Aging." Dr. Bortz's address was discussed by Dr. Ewald W. Busse, professor of psychiatry, Duke University and Dr. Maurice E. Linden, director, division of mental health, Philadelphia Dept. of Public Health.

NORTH PACIFIC SOCIETY OF NEUROLOGY AND PSYCHIATRY.—The annual meeting of the North Pacific Society of Neurology and Psychiatry was held in the Benjamin Franklin Hotel, Seattle, Wash., April 11-12, 1957. The following officers were elected: president: D. E. Alcorn, M. D., Victoria, B. C.; president-elect: J. W. Evans, M. D., Portland, Oregon; secretary-treasurer: R. M. Rankin, M. D., Seattle, Wash.

THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.—This Board announces the following schedule of examinations: New York, New York—December 16 and 17, 1957; San Francisco, California—March 17 and 18, 1958.

FIRST CANADIAN MENTAL HOSPITAL INSTITUTE.—For the past 8 years THE AMERICAN PSYCHIATRIC ASSOCIATION has organized an annual national institute for mental hospital and related institutional personnel. Lasting for one week, these Institutes have consisted of seminars and workshops focused on a variety of mental hospital problems. Canadian participation has grown larger each year, and action has now been taken to sponsor a similar meeting in Canada.

Working in co-operation, the APA and the CPA will jointly sponsor the first Canadian Mental Hospital Institute at the King Edward Hotel, Toronto, Ontario, January 20-24, 1958. A planning committee, un-

der the chairmanship of Dr. Mary Jackson, Toronto Psychiatric Hospital, has been set up which is working closely with the provincial directors of the CPA. The Canadian Institute will follow the main lines of its American counterpart and will receive organizational staff assistance from the APA Mental Hospital Service.

Program suggestions, advice and comments should be addressed to Dr. Mary Jackson, c/o Toronto Psychiatric Hospital, 2 Surrey Place, Toronto, Ontario.

DR. GUTTMACHER ISAAC RAY LECTURER.—Dr. Manfred S. Guttmacher, psychiatrist and chief medical officer of the Supreme Bench of Baltimore, Md., is the 6th winner of the \$1000 Isaac Ray Lectureship Award of THE AMERICAN PSYCHIATRIC ASSOCIATION, it was announced at the APA's annual meeting in Chicago. The Award is given annually to a psychiatrist, lawyer or judge for contributing importantly to better understanding between psychiatry and law.

As recipient, Dr. Guttmacher will deliver a series of lectures on psychiatry and the law, under the sponsorship of the Schools of Law and Medicine at the University of Minnesota, in the academic year 1957-1958.

The Award commemorates Dr. Isaac Ray, a founder of the APA, whose remarkable "Treatise on the Medical Jurisprudence of Insanity," published in 1838, was for many years the standard work on the subject.

FOUNDATIONS' FUND FOR RESEARCH IN PSYCHIATRY.—The Foundations' Fund for Research in Psychiatry wishes to announce that October 15, 1957, is the next deadline for the submission of applications for research fellowships and research teaching grants in psychiatry, psychology, sociology, neurophysiology, and other sciences relevant to mental health.

Interested persons and departments are invited to write for details to: Foundations' Fund for Research in Psychiatry, 251 Edwards St., New Haven 11, Conn.

DR. HEINICKE RECEIVES HOFHEIMER PRIZE.—Christoph M. Heinicke, Ph. D., of Portland, Ore., and currently senior research psychologist at the Tavistock Clinic in London, England, is this year's winner of THE

AMERICAN PSYCHIATRIC ASSOCIATION'S \$1500 "Hofheimer Prize" for outstanding psychiatric research, it was announced at the APA annual meeting in Chicago.

Dr. Heinicke's prize-winning research dealt with the effects of separating 2-year-olds from their parents. The research is considered of outstanding merit for the methodology of behavior measurement it developed.

The Hofheimer Prize was established in 1947 in honor of Lieutenant Lester N. Hofheimer of New York City, who lost his life in action in the Mediterranean in World War II.

DR. HOFFMAN DIES.—Dr. Jay L. Hoffman, associate clinical professor of psychiatry, George Washington University Medical School, and first assistant physician, St. Elizabeths Hospital, Washington, D. C., died following a heart attack at the hospital, May 4, 1957. His age was 47.

Dr. Hoffman was graduated in medicine from the University of Pennsylvania in 1934. He served overseas during World War II and attained the rank of lieutenant-colonel. He had charge of a psychiatric clinic in England. Following the War, he was named chief of professional services, Veterans Administration Hospital, New Bedford, Mass. Since 1953, he had been on the staff of St. Elizabeths Hospital, where in cooperation with the National Institute of Mental Health he was engaged in research. He was a fellow of THE AMERICAN PSYCHIATRIC ASSOCIATION and a diplomate of The American Board of Psychiatry and Neurology.

INTERNATIONAL SOCIETY FOR PSYCHOPHARMACOLOGY.—At the recent symposium on Psychotropic Drugs held in Milan, Italy, it was tentatively decided to form an International Society of Psychopharmacology, comprising the disciplines of psychiatry, pharmacology, neurophysiology and psychology. An organizational meeting will be held during the International Congress for Psychiatry in Zurich, Sept. 1-7, 1957. All those interested can obtain further information by writing to Herman C. B. Denber, M. D., Director of Psychiatric Research, Manhattan State Hospital, Ward's Island, New York City 35, N. Y.

JOINT MEETING OF ROYAL SOCIETY OF MEDICINE AND MEDICO-PSYCHOLOGICAL SOCIETY.—Immediately after the International Psychiatric Congress in Zurich, the Royal Society of Medicine and the Royal Medico-Psychological Association have organized a joint Anglo-American Symposium to give the opportunity to many psychiatrists in England to hear a group of eminent psychiatrists from America. This symposium will be held at The Royal Society of Medicine, 1 Wimpole Street, London, W. 1., on Tuesday and Wednesday, September 10 and 11, 1957. There will be both morning and afternoon sessions. Chairmen will be: Dr. R. W. Armstrong, president, R.M.P.A., on Tuesday, and Dr. William Sargant, president, psychiatric section of the R.S.M., on Wednesday.

A *limited* number of tickets will be available on application to: The Registrar, Royal Medico-Psychological Association, 11 Chandos Street, Cavendish Square, London W. 1., England.

ELECTROSHOCK RESEARCH ASSOCIATION.—At its annual meeting in Chicago, May 12, 1957, the Association elected the following officers for the year ending March 31, 1958: Dr. Lothar B. Kalinowsky, president; Dr. George A. Ulett, vice-president; Dr. Paul H. Wilcox, secretary-treasurer; Dr. Ernest H. Parsons (ex-pres.), Dr. William L. Holt, Jr. (ex-pres.), Dr. John D. Moriarty, and Dr. Maximilian Fink, councilors.

The annual prize for the best research paper presented at the scientific session of the Electroshock Research Association in 1957 was awarded to the paper: "Electroencephalographic Studies on the Effects of Electro-convulsive Shock, Experimental Stress and Subcutaneous Injection of Atropine on Adult Albino Rats," by T. Fukuda, J. A. Stern, and G. A. Ulett, St. Louis, Mo.

AMERICAN NURSES' FOUNDATION, INC.—This Foundation, established in 1955 by the American Nurses' Association exclusively for charitable, scientific, literary and educational purposes, has delineated 5 broad areas in nursing research in which investigation is urgently needed. Scholars interested in submitting applications for research projects in this field are invited to send an abstract

of their proposals to The American Nurses' Foundation, Inc., 2 Park Ave., New York, N. Y., by November 1 or March 1 of each year.

N. Y. STATE CRUSADE AGAINST CHRONIC ALCOHOLISM.—A \$168,000 program to attack the problem of chronic alcoholism will be undertaken during the coming year by the New York State Interdepartmental Health Resources Board, it was announced recently. The program will be directed along 4 major lines—education, research, training, and clinical demonstration. There are an estimated 500,000 excessive or problem drinkers in N. Y. State, and the program will encourage physicians, nurses, social workers, educators and teachers, through fellowships of \$300.00 each, to work on community alcoholism programs. This is just one of several projects planned by the Interdepartmental Health Resources Board to deal with alcoholism in N. Y. State.

CHARLES FREDERICK MENNINGER AWARD.—The American Psychoanalytic Association, at its annual meeting at Chicago, May 13, 1957, conferred the first Charles Frederick Menninger award on Dr. Charles Fisher, of the staff of The Mount Sinai Hospital of New York and training analyst of the New York Psychoanalytic Institute.

This annual award for original research in psychoanalysis was established a year ago by Dr. Karl A. Menninger and Dr. William C. Menninger of the Menninger Foundation as a memorial to their father, who was the founder of the original Menninger Sanitarium at Topeka, Kansas.

Dr. Fisher was thus honored in recognition of experimental work on the role of primary modes of perception in dream formation (J. of Am. Psyc. Assoc., Vol. 2, No. 3, 1954; Vol. 4, No. 1, 1956), by which he was able to verify some of the basic theoretical principles originally postulated by Freud in his work on dreams.

NATIONAL LEAGUE FOR NURSING.—At a meeting held under the auspices of the National League for Nursing at the Morrison Hotel, Chicago, May 6, 1957, a special panel dealt with the nursing needs in all cases of long-term illness. It was emphasized that the wide scope of nursing responsibilities now

embrace assistance to the patient and his family with their economic, social and emotional needs, as well as the physical requirements.

MILWAUKEE NEURO-PSYCHIATRIC SOCIETY.—The annual meeting of the Society was held on Wednesday, May 22, 1957. Newly elected officers for the coming year are: president: David Cleveland, M. D., Milwaukee, Wis.; vice-president: Keith Keane, M. D., Sheboygan, Wis.; secretary-treasurer: Edward Carl Schmidt, M. D., Wauwatosa, Wis.; councilors: Isaac J. Sarfatty, M. D., Milwaukee, Wis.; and J. T. Petersik, M. D., Winnebago, Wis.

NEW YORK BUILDS STATE MENTAL HOSPITAL.—Plans have been made for the first new mental hospital to be built by N. Y. State in 25 years. The \$70,000,000 institution, to accomodate 3,000 patients, is to be located in the Bronx, adjacent to the Albert Einstein Medical Center, the East Bronx General Hospital, and the East Bronx Tuberculosis Hospital.

According to operating plans outlined by Dr. Paul H. Hoch, Commissioner of Mental Hygiene, the hospital will serve the Bronx and its residents, providing both inpatient and outpatient care, including the new day hospital type of service, where patients spend the day participating in a regular therapeutic program and return to their homes at night.

The hospital will work in cooperation with the Albert Einstein College of Medicine, providing for the college resources for psychiatric teaching material and availing itself of the consultant services offered by the school's highly qualified specialists. It will be staffed with its own full time psychiatrists.

The Department of Mental Hygiene has worked closely with the architects on plans for the various buildings, which are based upon research into modern mental hospital construction, and incorporate a number of new features. All of the planning has been flexible to accomodate new developments in treatment.

The hospital will operate a school of nursing offering a complete 3 year basic course, and affiliate training for general hospital students.

STATUS AND IMPROVEMENT OF CLINICAL DRUG EVALUATION REPORTS.—A 22-page report has been issued on the proceedings of the working conference held by the recently established Psychopharmacology Service Center of the National Institute of Mental Health. The conference, held at Washington, D. C. in January was arranged in collaboration with THE AMERICAN PSYCHIATRIC ASSOCIATION.

The major purpose of the conference was to review the problems related to the reporting of clinical psychiatric drug evaluation studies and to consider the ways in which reports might be made more informative and useful. To this end, 5 committees were formed: 1. Patient Selection and Description; Chairman, Harry Freeman. 2. Evaluation of Change; Chairman, Ivan F. Bennett. 3. Description of the Treatment Setting; Chairman, Jay L. Hoffman. 4. Drug Therapy and Toxicity Reactions; Chairman, Heinz Lehmann. 5. Editors; Chairman, Roy P. Grinker.

A recommendation was made to establish a new journal to publish works concerning drugs used in the treatment of psychiatric illness and whatever clinical data are developed from pharmacological techniques applied to mental illness.

For further information, write to Jonathan O. Cole, M. D., Chief, Psychopharmacology Service Center, National Institute of Mental Health, Bethesda, Md.

NEW JERSEY NEURO-PSYCHIATRIC INSTITUTE.—The Edward Strecker Building at the N. J. Neuro-Psychiatric Institute, Princeton, N. J., was formally dedicated June 28, 1957, as announced by Dr. Robert S. Garber, medical director of the Institute. The building is named in honor of Dr. Strecker, Emeritus Professor of Psychiatry, University of Pennsylvania. Dr. Strecker serves as consultant to the Surgeons General, U. S. Army and U. S. Navy, and has also served as consultant to the Secretary of War for the Army Air Force. He has been recently appointed as the first professor of psychiatry at the Seton Hall College of Medicine and Dentistry, Jersey City, N. J.

Dr. Lauren H. Smith, physician-in-charge and administrator, Institute and Department for Mental and Nervous Disease, Pennsyl-

vania Hospital, Philadelphia, made the principal address at the dedication ceremony.

The new building will include a small unit for short-term treatment, another for longer-term treatment, and an outpatient division for 50 patients. The objective is a vitally improved service in the field of community mental health.

FIRST AMERICAN CONGRESS OF LEGAL MEDICINE AND LAW-SCIENCE PROBLEMS.—

Dr. Hubert Winston Smith, director of the Law-Science Institute, The University of Texas, has announced the "First American Congress of Legal Medicine and Law-Science Problems" to be held at the Hotel Morrison, Chicago, Monday, July 8-20, 1957, for benefit of lawyers and physicians concerned with personal injury problems. The effort is the most ambitious one of its kind ever undertaken in an English-speaking country. It will feature 165 distinguished lecturers, drawn from the ranks of top medical specialists and trial lawyers. Each week the registrant may take a complete Basic Course or an Advanced Course without substantial duplication of instruction between the two weeks.

The Congress is an attempt to bring the authoritative medicine of the clinic and hospital into the arena of the Law by providing much-needed criteria of proof and instruction in the field of medicolegal trial technique. Each person registering for the course will be eligible to count the hours toward a Master of Law-Science Degree to be awarded by the Law-Science Academy of America. This will be the first time in history that lawyers and physicians have been able to work toward a common degree, based upon inter-relations of Law and Science.

FIRST NATIONAL HEALTH SURVEY.—In May Public Health Service interviewers commenced a nation-wide survey of selected households in every state to obtain data regarding the amount of accidents, hospitalization, and medical and dental care occurring in the families and the length of time that the persons involved have been prevented from carrying on their occupations.

An average of 3,000 households will be visited per month, and the final statistics will be published for the nation as a whole, and

for each of the 11 established geographic areas. The report will supply physicians, research workers, insurance companies and hospital personnel with urgently needed facts on the health of the general population.

BIBLIOGRAPHY OF GROUP PSYCHOTHERAPY.—A comprehensive bibliography of published papers and books on group psychotherapy has recently been issued by the Beacon House Press, Box 311, Beacon, N. Y., edited by Raymond J. Corsini and Lloyd J. Putzey, and covering the years 1906 to 1956.

This new compilation supersedes the first published bibliography in the field of group psychotherapy by Dr. Joseph I. Meiers, issued in 1945.

PSYCHIATRIC GLOSSARY.—The American Psychiatric Association Committee on Public Information has recently published a 48-paged psychiatric glossary of terms in an effort to transpose the technical terminology of psychiatry into popular language. Dr. Henry P. Laughlin, a member of the committee assembled a collection of terms, which the Committee subsequently defined in simple language. It is hoped that the glossary will aid reporters in presenting information about psychiatry to the general public, and clear up widespread misconceptions about psychiatric words and concepts.

The new A.P.A. glossary is the first of its kind since the publication of Richard H. Hutchings *Psychiatric Word Book* in 1930. Copies may be obtained from the Washington office of the A.P.A. for \$1.00.

PSYCHIATRIC RESEARCH REPORTS No. 6.—Papers presented at the Western Regional Research Conference of the A.P.A. held in Los Angeles January 26-27, 1956, are now available in printed form from the Washington office of the A.P.A. These papers were arranged around the general topic, "Application of Basic Science Techniques to Psychiatric Research" and are edited by Dr. Robert A. Cleghorn, Montreal. The topics of individual papers cover a wide range, from the strictly laboratory type of investigation to the clinical to the behavioristic sciences as represented by investigations of the whole animal organism.

OFFICIAL REPORTS

COORDINATING COMMITTEE ON THE TECHNICAL ASPECTS OF PSYCHIATRY

This report to the membership of the A.P.A. May 14, 1957, covers the highlights of 8 Committees on the Technical Aspects of Psychiatry. All these committees met last fall. Seven met again earlier this week, and the eighth committee had a special meeting in March. In addition, the chairmen of these 8 committees have met as a group to discuss mutual problems and to plan overall strategy, to coordinate their work with that of other committees of the Association.

A very brief report of the activities of each Committee prior to the May 1957 meeting follows:

I. *The Committee on Aging*; Ewald W. Busse, Chairman, had its first meeting in October 1956. Plans were formulated to include an evening round table discussion during the annual meeting devoted to the "Psychiatric Aspects of Aging, Prevention and Treatment," and a symposium concerned with the problems of aging. A questionnaire was distributed to the members of the A.P.A. via *The Mail Pouch* to determine the extent of interest and activities among the members in this field. Approximately 1,100 questionnaires were returned indicating considerable interest. The data so obtained are being analyzed and the results will be available at an early date.

Acting upon a specific request, attention is being given to the collection of information as to requirements for the care of the aged in mental hospitals. The committee will cooperate with the editorial staff of *Mental Hospitals*, anticipating that an issue of this publication will be devoted to this complex subject.

II. *The Committee on Child Psychiatry*: George E. Gardner, Chairman. "During the past year this committee has been working in two areas: 1. that of residence inpatient psychiatric treatment of children; 2. the rotational training program in child psychi-

atry for fellows in training in general psychiatry.

The Committee has met with the Committee on Medical Education and are about to make recommendations to the Council regarding block or concurrent training programs for fellows in training in general psychiatry who wish to obtain orientation and education in the children's field."

III. *The Committee on the History of Psychiatry*: Robert S. Bookhammer, Chairman. "In addition to our meeting in the fall of 1956, our committee also had a meeting on March 9, 1957. Our several committee members have been working throughout this year on a joint project and there is still work to be done in preparation for the exhibit on Historical Landmarks in Research in Schizophrenia in the United States, to be presented at the International Congress on Psychiatry in Zurich, Switzerland, September 1957. It will be annotated in both English and French following the custom of previous international meetings. The exhibit is not definitive nor comprehensive but is designed to show the scope and quality of research since 1800."

IV. *The Committee on Medical Education*: Milton Rosenbaum, Chairman, "The committee sponsored and organized a Round Table meeting during the May 1957 meetings on 'Pros and Cons' for a Straight Psychiatric Internship, or a Mixed Internship with the Inclusion of Psychiatry." The subject of medical education during the internship is very much in the limelight these days and therefore the Round Table is quite timely.

Dr. Brian Bird of the committee, has been appointed to serve with the *ad hoc* committee of the A.P.A. on General Practice in liaison with the American Academy of General Practice.

Several meetings have been held between the *ad hoc* committee of the A.P.A., made

up of the members of the Committee on Medical Education, and the *ad hoc* committee of the American Psychoanalytic Association, to discuss problems of mutual interest regarding psychoanalytic training during the residency period. The two *ad hoc* committees met again during the May meetings."

V. *The Committee on Public Health:* Roger W. Howell, Chairman, "1. Members of the Committee reviewed summary reports of different community surveys prepared by Dr. Blain and his staff, in preparation for discussing their future as a regular activity of the Central Office staff. A member of this committee participated in the survey conducted in the city and county of Saint Louis, Mo.

2. The Committee prepared a summary of its opus on the relationship between infectious diseases and mental retardation, which summary is to be presented at the 1957 meeting of the American Association for Mental Deficiency. It is hoped that it will be published.

3. Sponsored jointly with the Mental Health Section of the American Public Health Association a panel presentation on the subject "Public Health Aspects of the Tranquilizing Drugs." A member of the committee presented a summary of the presentations. This panel presented their material at the annual meeting of the American Public Health Association at Atlantic City in November, 1956.

4. Committee members continued their reviewing of the material so far assembled for our booklet for public health administrators entitled "How To Do It," referring to community mental health. It is hoped that the committee following discussions in May will be ready to prepare the booklet in its final form."

VI. *The Committee on Rehabilitation:* formerly known as the Committee on Medical Rehabilitation, Benjamin Simon, Chairman. "In addition to considering, as it does regularly, the progress of the Pilot Study on Rehabilitation (which is now in the last part of the evaluation phase) and the Round Tables for the next and succeeding years, the Committee undertook to set forth (at the request of Lucy D. Ozarn, M. D., director

of the Architectural Study Project) the philosophy of treatment which might become the ultimate basis for architectural development. The Committee will continue in this activity for the next year, at least.

The Committee undertook to act as an advisory committee to the study on Adjunctive Therapies being set up at Washburn University, Topeka, Kansas, under the direction of Dr. William H. Key, supported by a grant from the office of Vocational Rehabilitation. At its next meeting, the Committee will have as its guest Dr. Key, who will discuss the broad outline of the study.

The Chairman of the Committee represented THE AMERICAN PSYCHIATRIC ASSOCIATION on the advisory committee on Physical Therapy Education of the Council on Medical Education and Hospitals of the American Medical Association which met in Chicago on February 12, 1957. Dr. Simon was made a member of the four-man executive committee of the advisory committee, which is now fully organized and will function continuously.

A similar advisory committee on Occupational Therapy Education is being formed by the American Medical Association and the appointment of Dr. Simon to this committee has been recommended by the Council."

VII. *The Committee on Research:* Nathan S. Kline, Chairman; "1. A survey is being made of the positions available in state hospitals for research in psychiatry, in respect to both number, salaries and availability.

2. Ciba Pharmaceutical did not renew its support for the Psychiatric Research Reports and negotiations (subject to approval of Council) are being completed with another pharmaceutical house.

3. Five years of support were obtained for a research lectureship, to be known as the Adolf Meyer Research Lecture to be given at the annual meeting.

4. Preliminary meetings have been held and plans are being formulated for a National Conference on the subject of Psychiatric Research, its direction, financing, and training of personnel.

5. Regional Research Conferences were held in Philadelphia, Syracuse, and one is

planned for later this month at the University of Oklahoma.

6. The Committee on Research co-sponsored a meeting with the American Public Health Association on problems involving epidemiology of mental disorders at the annual meeting of the AAAS."

VIII. *The Committee on Therapy*: Paul H. Hoch, chairman, has continued to discuss "quite a number of issues which were referred to the Committee either by other committees of the Association or by outsiders.

The Committee was also engaged in revising the standards of electroshock therapy which had to be brought up to date.

The Committee began to organize a guide for physicians to psychiatric services which will be country-wide. Material has been collected about some of the states and this work is continuing. We hope that when it is completed a directory can be organized giving

the main psychiatric resources of the United States insofar as they relate to the general practice of medicine.

The Committee also engaged in discussions on the possibility of organizing a short manual on psychiatric therapies indicating their proper places in present psychiatric practice. No final decision was reached whether or not the Committee would undertake this project.

In summary, I wish to point out that these various committees have not only been working closely with other committees of our Association, but also with other state and national organizations. I wish to take this opportunity to publicly thank the chairmen and the members of these committees who have worked so faithfully and arduously during the past year. I am sure our entire organization will benefit for many years as a result of their splendid contributions.

FRANK J. CURRAN, M. D.,
Chairman.

AEROPHOBIA

Some are as much afraid of fresh air as persons in the hydrophobia are of fresh water. I myself had formerly this prejudice, this aerophobia, as I now account it. And dreading the supposed dangerous effects of cool air, I considered it as an enemy and closed with extreme care every crevice in the rooms I inhabited. Experience has convinced me of my error. I now look upon fresh air as a friend; I even sleep with an open window. I am persuaded that no common air from without is so unwholesome as the air within a close room that has been often breathed and not changed. . . . And I find it of importance to the happiness of life, the being freed from vain terrors, especially of objects that we are every day exposed inevitably to meet with. . . . It is to be hoped that in another century or two we may all find out, that it [fresh air] is not bad even for people in health.

—BENJAMIN FRANKLIN

FORGETTING

To know how to forget is more a matter of luck than of skill. The things which are better forgotten are those we remember best; memory is not merely a rogue in failing us when it is most needed, but a tool in turning up at inconvenient times; in matters which will prove troublesome, it is long, and in those which ought to be a source of pleasure it is headless. Sometimes the cure for misfortune consists in forgetting it, and the remedy is forgotten; it is advisable, therefore, to train the memory to good habits, for it can turn life into a heaven or a hell.

—BALTASAR GRACIAN
(The Oracle, 1647)

BOOK REVIEWS

SLEEP. By *Marie Stopes*. (New York: Philosophical Library, Inc., 1956. \$3.00.)

Dr. Stopes prefaces her book with: "No expert in the world really understands sleep or knows what it is. Nor do I: but in spite of that I feel that in this book, small though it is, I do contribute some facts and fancies many people may like to know."

After this the author then fails to distinguish that which she considers fact from that which was intended to be more fanciful. In this reviewer's opinion the latter predominates throughout. Since it is the curse of error that at least two statements are required to refute every one presented originally, and since there are so many ideas that are not validated, this book can best be reviewed by quoting a few of these passages for the scrutiny of the reader:

"Personally, I think it is a crime of the first magnitude to wake anyone, save in an emergency. I should lay down as an absolute rule that *no* child should be waked, not even a child of school age. Sleep is of *far* more value to a child than lessons. Anyone who continuously finds it necessary to use an alarm-clock, or be waked, should realize it is a sign that more sleep is needed, and should go to bed earlier." (pp. 5)

The book abounds in personal opinions such as this:

"One may have to sleep on the bare ground, or on a board, and millions of people do. We are, however, civilised communities and should make use, every time we can, of the best that our civilisation provides for us. A soft mattress is one of the good things we can now readily obtain.

"But do *not* go too far with the idea that modern things are necessarily really good and civilised. Often they lean backwards. The soft foam rubber mattress is an example of a modern 'advance' to be avoided by all who value their health. It is pernicious. Do *not* use any rubber mattress, and do *not* have rubber-tyred wheels on your bedstead. Why? Because rubber is an insulator, and cuts you off from electric currents of the earth with which you should be in contact. Many, sadly many, people are insulating themselves incessantly. Rubber-soled shoes all day, and then rubber covering to their floors, small wheels with rubber tyres on their beds—alas, poor things, they are being devitalised. No wonder millions at the end of the day feel limp and exhausted yet neither ready for, nor able to, sleep." (pp. 31)

Is this fact or fancy? The author sounds serious! This question might be passed over if the book then presented a few validating facts, but two pages later one reads:

"Beds are generally placed to suit the build of the room but this is often wrong. The place of the bed should be determined by something more fundamentally important, that is the direction of the

North. The head of the bed should be north or south, and the bed should extend between these two poles. It is comparatively unimportant whether the head or the feet are at the north end of the bed, but it is very important indeed that the extension of the body should lie along a line either south-north or north-south. Few people are now aware that we do not have only five senses, as children are senselessly taught in school, but we used to have, and some few people still have, other senses, and one of these is a sense of the north. It is just as clear and definite a sense as any other. One *sees* the wall in front of one, one *hears* the bird calling, and one *magnetates* the north. Magnetates? A new word, you say. Yes. A new word, and I am coining it here and now for a very real sense. I know about it, for I possess it. It is in my spine that I magnetate the north, between my shoulder-blades and hips. I used to have this sense so intensely that I could be blindfolded in a fog on a desolate moor and twisted round a great number of times, and could at once point to the exact north. This was tested by geologists with a compass and was often of great use to me. Since my back was broken and my abdominal walls cut, I am not so acutely sensitive to the north as I was, but still I generally feel it. If by chance I visit a house where my bed is set east-west, even though there may be nothing in the curtained room to indicate this, once I lie in the bed trying to sleep, I very soon suffer and so find out. I do not sleep till I have popped out of bed and shifted it to the north and south direction. If it is too heavy for me, I lie diametrically or slantwise across it till I am north and south, and even though this may make the bed-clothes rather uncomfortable, I am then able to sleep."

Anticipating the difficulties her colleagues might have swallowing the preceding statements, the author rebuts as follows:

"There are many, certainly the majority of ordinary people and also most medical doctors, who will scoff at the idea that the north and south placing of any bed is important. That does not show that they are wise, or right, or 'scientific'; it merely proves that they are ignorant of one of the existing human faculties. Many people who are quite unconscious of the faculty have a disturbed feeling which appears unaccountable when their beds are wrongly placed. I think this is because they feel subconsciously what some feel consciously.

"In all my life I have never found a living person who feels the north as acutely as I do . . ."

Concerning the fabric of bed clothes the author does not hesitate to decree:

"It is dangerous that cellulose fabrications should be allowed to call themselves 'pure silk' and so deceive women into thinking they are getting silk when they are not. The only pure silk in the world is made by silk worms and gives indescribable com-

fort undreamed of by the wearers of 'silk' and nylon. Real silk-worm silk is a delicate web for the capture of sleep."

About the effect of daylight saving time on sleep the author has more firm opinions. Another crime has been perpetrated against the sleep of civilized man by this practice.

Among causes for insomnia the author lists cold feet, noise, grief, worry, etc. Comparatively speaking, this is a refreshing factual interlude in the fancy replete in *Sleep*.

For those who intend to spare themselves the soporific chore of reading *Sleep* I quote a final gem:

"People who find difficulty in going to sleep, and have used all the usual dodges without success, might try the effect of having a large grandfather clock in the bedroom. A small, quick-ticking grandfather clock is no use. Before buying it, test it by having the ticks and your own heart-beats per minute each counted when you have been sitting quietly in a chair for five minutes. Unless the clock's ticks are materially slower than your own heart-beat, do not buy it. To act as a soporific your clock must be *markedly* slower than your own heart-beat when awake, or it will not be slower than your heart-beat when yours is slowed down in sleep. The effect of the slow grandfather clock is superlatively soothing and sleep-enticing."

JOSEPH J. PETERS, M. D.,
Philadelphia, Pa.

KLINISCHE ELEKTROPATHOLOGIE: I. Kritische Sammlung Elektropathologischer Gutachten Aus Interner Sicht. By Dr. S. Koepfen; II. Die Neurologie Des Elektrischen Unfalls Und Des Blitzschlags. By Dr. F. Panse. (Stuttgart: Georg Thieme Verlag, 1955. DM 33.-)

This work on Clinical Electropathology is part of a series on social and industrial medicine. The volume consists of 2 monographs by separate authors presenting essentially the same subject from different angles. The 2 independent monographs reached the publisher at about the same time and were united in a volume purposely without integrative editing by the authors. The texts complement rather than repeat each other. Slight differences in the approach would benefit rather than confuse the critical reader, in the opinion of the editors.

The first monograph, by Dr. Koepfen, bears the title, "A Critical Review of Electropathological Case Histories with Special Regard to Medico-legal Problems." It is a systematic presentation of the subject in a textbook-like manner, woven around case histories. The first chapter deals with physical and technical data. The clinical sections discuss cardiac, vascular, endocrine, respiratory, autonomous and central nervous disturbances in their relationship to electrical accidents. The clinical entities are presented not only as sequelae of electrical traumata, but also the outcome of electrical accidents are discussed in patients with pre-existing conditions in most of the above-mentioned categories.

The second monograph, by Dr. Panse, bears the title, "The Neurology of Accidents Caused by In-

dustrial Electricity and by Lightning, Including a Chapter on Electromagnetic Waves and Atomic Energy." This monograph like the first one starts with an electrophysical and technological introduction. In the clinical portion separate sections deal with the initial and the late results of electrical accidents. Of some interest to psychiatrists is the well documented discussion of the psychological impact of being struck by lightning or hit by industrial electricity (e.g. a very short episode of mild to severe impairment of awareness was frequent, retrograde amnesia however was unusual; occasional sensory experiences occurred similar to the epileptic aura; psychological reactions varied according to the personality and the circumstances; a temporary stupor state with inability to move was common when hit by a bolt of lightning, even if injury was light). The neurological and pathological sequelae discussed include cerebral oedema, cerebral degenerations (mostly basal ganglia), brain injuries due to burning, progressive atrophies of the spinal cord, also thermoelectric damages of the spinal cord and peripheral nerves. Therapeutic electric-shock receives but a few passing remarks in this book on clinical electropathology. The reason for this apparent neglect is a gratifying one: i.e. electroshock therapy is hardly an electrical hazard. The only neurological sequelae mentioned by Panse were the rare occurrences of an activation of latent epilepsy following a series of electroshock treatment (about 60 cases in the literature), and occasional cerebrovascular accidents during therapeutic convulsions.

Both monographs are well illustrated and documented by case histories, photographs, charts and diagrams. The presentation of the subject is thorough and authoritative, but peripheral to the interest of the psychiatrist. However, for those physicians who deal with the management, the forensic aspects or compensation of electrical casualties this volume is an excellent text and reference book.

A. BONKALO, M. D.,
Toronto Psychiatric Hospital.

A MANUAL OF PSYCHIATRY (3rd. Ed.). By K. R. Stallworthy. (New Zealand: N. M. Peryer, Ltd., pp. 324, 1955.)

This volume represents a brief textbook of psychiatry, obviously written for the beginner and apparently written for not only doctors but nurses and others working in a psychiatric institution. On the whole, the material is presented in accordance with the best thinking of American psychiatry and is well up to date.

The first chapter deals with "admissions" and "discharges" and is a discussion of the situation in New Zealand. You can be discharged as "recovered," "relieved," or "unrecovered." There are 2 brief chapters on "The Mind in Health" and the other on "Abnormal Psychology" which do not give the material in much detail. In the chapter on "Abnormal Psychology" less than 2 pages are given to psychoanalytic formulations. Likewise, in the chapter on "Psychotherapy" about 3 pages are

given to psychoanalysis, with about one of these pages devoted to the ideas of Jung and of Adler.

As a textbook for nurses and attendants and giving some of the material of a special textbook of psychiatry it is too condensed, oversimplified, and hardly to be compared with our best American textbooks on the subject.

K. M. B.

FRAGMENTS OF AN ANALYSIS WITH FREUD. By *Joseph Wortis*. (New York: Simon & Schuster, 1954. \$3.00.)

Twenty years after the event, Dr. Wortis has written one of the most fascinating and at the same time, important documents in modern psychiatric history. It is the almost verbatim account of approximately 4 months of didactic analytic sessions with Sigmund Freud. Because of the nature of the relationship, and the character of the analyst and analysand, there apparently resulted greater revelation of the former's thought and feeling than of the latter's. No matter what the ultimate judgment of history, Freud is one of the most important figures in psychiatric history and indeed in arts and letters, and a cultural figure of the first magnitude. A book, therefore, which gives intimate details not only of his very human characteristics, but at the same time reveals Freud's thoughts on his discipline and the world, as well as his colleagues, makes for reading which is almost breathless in pace.

The author, soon after becoming the recipient of a rather unique and important fellowship under the supervision of Havelock Ellis and Adolf Meyer decided that some psychoanalytic experience would be valuable to him. Arrangements were made with Freud and thus began what was probably one of the strangest analytic relationships extant. From the very beginning, the author kept a series of extensive notes on the interviews including verbatim quotations of the great teacher. The book is replete with little revealing remarks such as the importance of the classical chair-behind-the-couch arrangement to assure ease in the patient, "besides, I don't like to have people stare me in the face." It is greatly tempting to offer one quotation after another on psychiatry, art, finance, women, literature, America, christianity, physiology, jews, communism, colleagues, and above all, himself.

At the outset financial difficulties arose because fellowship funds were not immediately forthcoming and Freud's concern about his fees made matters somewhat touchy. This was not helped by the author's later request for a receipt, something one simply did not ask of a continental physician. The brash young American was apparently sufficiently irritating and at the same time intellectually stimulating that Freud, who was never known for his passivity during analysis, poured forth a wealth of comment on every topic under the sun. By actual count, almost a hundred different areas are enumerated in the index. Freud was an old man, ill, irritable, but still intellectually vigorous and interested in his environment. He was vain, dogmatic, and at times petty, but always interesting. His

biting and almost vicious comments on his colleagues, Stekel, Hirschfeld, Ellis and others are, if nothing else, refreshingly frank.

It is difficult not to agree with Havelock Ellis's remarks after reading the collected notes, "I consider the notes most valuable and that they ought someday to be published after Freud's death. . . . Their value is that they constitute an analysis of Freud and a precise revelation of his technique. I do not suppose that any similar record—even if it exists—will be published, as the ordinary patient would not of course care to give himself away." Adolf Meyer concurred with this statement and so must the reader.

BENJAMIN PASAMANICK, M.D.,
Columbus, Ohio.

MEDICAL ASPECTS OF TRAFFIC ACCIDENTS. Proceedings of the Montreal Conference. Edited by *Harold Elliott*. (Sun Life Assurance Company of Canada, 1955, pp. 511. \$7.00.)

This book of 511 pages consists of the proceedings of the conference held at McGill University, May 4 and 5, 1955. The subject matter is broad in scope and consists of the papers and discussions of the various participants in the conference.

This conference with Dr. Harold Elliott as the driving force represents a new and worthwhile approach in medicine marking a transition from the position of repairing the injured to an attempt at understanding the basic problem with prevention as the ultimate aim.

Although there have been previous approaches to this problem by various specialties within the profession attacking that section of the problem apparently related to their field of knowledge, this represents the first over-all gathering together of a large and relatively heterogeneous group within the profession to discuss all aspects of traffic accidents that have apparent medical significance.

Because of its very nature the subjects dealt with have little in common but the central theme of a contribution to our knowledge of understanding, preventing and alleviating the results of traffic accidents.

Of greatest interest to psychiatrists will be Chapter 8 dealing with the "Behaviour Aspects as a Cause of Traffic Accidents" with the subtitle of "The Role of the Psychiatrists." This consists of 2 papers, the subsequent discussion and the recommendation forwarded by the group. Dr. A. Canty presents the experience of the Psychopathic Clinic with the Recorders Court in Detroit, Mich., with an interesting breakdown of the psychiatric diagnoses encountered in a psychiatric clinic functioning on a referral basis. The report by Dr. I. Brody of personality studies carried out on a sample of cases referred because of traffic violations as compared with a group of "good" drivers. The preliminary findings reported support amply the concepts derived by more restricted approaches to the problem; namely, that "the basic problem is psychological, a matter principally of emotional and social adjustment."

While this book does not make easy reading be-

cause of the nature of its origin, it does represent an outstanding approach to a problem which previously received little attention and encouragement in medicine. It should serve as a most valuable reference source as well as a preliminary model for future studies.

G. E. HOBBS, M. D.,
University of Western Ontario.

LEWIS CARROLL. By Derek Hudson. (London: Constable; Toronto: Longmans, Green & Co., 1954. \$4.25.)

Lewis Carroll died in 1898. He was spared the ignominy of the twentieth century that Saint-Exupéry hated so fatally. There must have been affinity there—*Alice* and *Le Petit Prince*!

Hudson's book was needed. It is an excellent antidote to the pronouncements of Florence Becker Lennon in her book, *Victoria Through The Looking Glass* (scholarly as it is, with its 22 pages of bibliography). New York Times reviewer Orville Prescott says that despite her "prodigies of research" the Lennon book is "disappointing and tedious." He speaks of her "fruitless Freudian probings" and her "heavy-handed psychiatric jargon." These gratuitous interpolations by the author impair a book which otherwise contains useful information about Lewis Carroll.

The Hudson book does not undertake such interpretations. It is factual, objective, lets the story tell itself—altogether a wholesome and delightful book, undoubtedly the best study of that unique personality, Lewis Carroll, to date. The *Diaries of Lewis Carroll* published in 1954 and much unpublished material in possession of the family, as well as a great many letters from other sources and a mass of documents recently discovered at Christ Church, Oxford, were all made available to the author who feels that his work may be regarded as the definitive biography.

The word unique is not used idly in speaking of Lewis Carroll, not in the sense of uncommon or rare but rather in the sense of the only one of the kind. A full consideration of this various man can hardly fail to establish this estimate. He was a polymorph artist, an inimitable story teller for children up to age 99, a famous photographer, when photography was new (Helmut Gernsheim calls him "the most outstanding photographer of children in the 19th Century"), clever illustrator (he did the pictures for the original manuscript of *Alice*), poet, author, devotee of the theatre and opera; in addition, a scientist, authority in mathematics and logic (lecturer in mathematics at Christ Church, published *Symbolic Logic*), besides all this, a clergyman. In this profession he followed in his father's footsteps; also it was necessary to be in orders to become an Oxford don in the mid-nineteenth century.

Charles Lutwidge Dodgson, born 1832, was the third of 11 children and the eldest son. All his life he was a stammerer and this handicap propelled both his teaching and preaching. At 13 he was sent to Rugby where he spent almost 4 unhappy years.

His superior abilities won no respect from his fellow students. He was sensitive and shy and a teasing victim. At 18, just after being entered at Oxford, he suffered a sore loss in the death of his mother, many of whose quieter, feminine qualities were reflected in her son.

Fondness for children was a dominant characteristic of Lewis Carroll from his early years. He "carried his childhood with him." Children were naturally drawn to him and his extraordinary gift for entertaining them endeared him to them, and their attachment to his person amounted at times "almost to adoration." He once remarked, "children are three-fourths of my life." And on another occasion he spoke of "the hundred or so of child-friends who have brightened my life." The children were almost exclusively preadolescent little girls, and as maturity approached interest on both sides as a rule subsided. As he explains in one of his letters, "Usually the child becomes so entirely a different being as she grows into a woman, that our friendship has to change too: and that it usually does by gliding down, from a loving intimacy into an acquaintance that merely consists of a smile and a bow when we meet!" In a few cases child friendships continued mutually to the end of his life. In an appendix to the present book will be found letters from several of his child friends written after his death describing those delightful and idealized early experiences that lived on as cherished memories. With the rare exception he was not interested in little boys. "I am fond of children," he said, "except boys. . . . To me they are not an attractive race of beings."

It is questionable that Lewis Carroll felt for any woman the kind of love that commonly leads to marriage. From his twenties on he occasionally spoke—and that not casually—of the improbability that he would ever marry. He never did. Ellen Terry was one of his child friends and his devotion to her and her art continued through the years. In a letter in later life Ellen Terry wrote, "He was as fond of me as he could be of anyone over the age of ten."

Lewis Carroll was an aesthete and a perfectionist. He was a rigid self-disciplinarian. He examined his motives with utmost scruple and his integrity was unquestioned. He worshipped beauty. In Cologne Cathedral he was so overcome emotionally by the majesty of the soaring columns and noble arches that he "sobbed like a child." And it was children that he loved most, children in "that blissful innocent state" of their early years; with his dual nature he could associate with them as of their own age level and also as the protective grown-up to guide and amuse.

Of all his child friends it was Alice Liddell, daughter of the Dean of Christ Church that impressed him most profoundly. When he first saw this lovely child she was only 4. "I mark this day with a white stone," he said. This was his way of indicating memorable occasions. It was to her and for her that he told and wrote the marvellous stories in the *Alice* books. She was their inspiration, and but for that ideal relationship these stories would

never have been written and some of the finest things in the world's literature would not have come into being.

Professor York Powell, an Oxford contemporary, has drawn a fine pen picture of Lewis Carroll: "The quiet humour of his voice, a very pleasant voice, the occasional laugh—he was not a man that often laughed, though there was often a smile playing about his sensitive mouth—and the slight hesitation that whetted some of his wittiest sayings . . . his kindly sympathies, his rigid rule of his own life, his unselfish love of the little ones, whose liegeman he was, his dutiful discharge of every obligation that was in the slightest degree incumbent on him, his patience with his younger colleagues, . . . his rare modesty, and the natural kindness which preserved him from the faintest shadow of conceit, and made him singularly courteous to every one, high or low, he came across in his quiet academic life,—a good teller of anecdote, . . . a fantastic weaver of paradox and propounder of puzzle, a person who never let the talk flag, but never monopolized it, who had rather set others talking than talk himself, and was as pleased to hear a twice-told tale as to retell his own store of reminiscence. . . ."

And the late Viscount Simon in his recollections in an appendix: "The truth about Lewis Carroll is that he was always engaged in genially pulling somebody's leg and he did this very amusingly by propounding a comic mathematical problem to a non-mathematical mind. . . . I think he found the Canons of Christ Church easy meat!

"His parody of Euclid's third 'Postulate' is a good example of his wit. The Postulate runs: 'Let it be granted that a circle can be described about any centre at any distance from that centre.' He transformed this into: 'Let it be granted that a controversy can be raised about any subject at any distance from that subject.' How true that is!"

The author of this book covers, with full documentation, all phases of the life and work of this remarkable mathematician-logician-poet-photographer-storyteller-friend and entertainer of children, who at home was C. L. Dodgson, but to the ends of the world was Lewis Carroll.

It is pleasant to recall that in 1932 Mrs. Alice Liddell Hargreaves, at the age of 80, left her English home and came to the United States to attend a series of celebrations of the 100th anniversary of the birth of Lewis Carroll, and to receive from Dr. Nicholas Murray Butler, president of Columbia University, the degree of Doctor of Letters. She recalled the incomparable and unforgettable hours when she, a little girl of 10, listened to Lewis Carroll spinning his magic to the delight of her and her sisters. "He was the kindest of people to small children," she said.

Persons in the United States have more than one reason for celebrating the Fourth of July. July 4, 1862 was another birthday. It was on a river-party that day that the *Alice* stories began.

To the T.B.M. or other citizen troubled by the *Storm and Drang* of our unquiet times and who feels that possibly a little psychotherapy might do

him good, one might well, in agreement with the views of our late colleague, Paul Schilder, recommend as a tranquilizing potion a few pages from *Alice in Wonderland*.

This book about Lewis Carroll should have been reviewed earlier, but it came to hand only recently.

C. B. F.

THE CLINICAL INTERVIEW. VOL. II: THERAPY. By Felix Deutsch and William F. Murphy. (New York: International Universities Press, 1955. \$7.50.)

This second volume of Drs. Deutsch and Murphy's ambitious undertaking is devoted to therapy and is subtitled, "A Method of Teaching Sector Psychotherapy." Unfortunately the impression that the contents of the first volume did not justify the comprehensive title is not corrected by the second part, and there is no indication that further volumes are in preparation (Am. J. Psych., 113:95-96, 1956). The first chapter presents an erudite and concise outline of the method, but it seems to this reviewer that the distinction between sector psychotherapy and other psychotherapy is much more meaningful to the advanced and experienced therapist than to the trainee. The same must be said of the therapeutic sessions presented in subsequent chapters. They give evidence of the greatest skill in interviewing based on extraordinary familiarity with personality dynamics and analytic concepts, which cannot be copied or acquired quickly by relatively inexperienced trainees and young psychiatrists. There is no discussion of the teaching value of these interviews, let alone a critical evaluation of either the teaching method or of the therapy itself. The absence of such discussion is most striking at the end of Chapter 5 which presents an interview with a borderline psychotic patient, one that could hardly be considered therapeutic in retrospect. In the brief follow-up statement the reader learns that this patient later becomes psychotic, but the interview is entitled "Reticence in the Interview," as if only the technical aspects were to be considered. Neither volume dispels the general impression that abbreviated forms of therapy require deeper understanding, greater skill, and wider experience than prolonged and more detailed psychotherapeutic efforts. In the latter the definition of goals may be less precise and can evolve gradually while working with the patient. This is easier for the trainee whereas early and therapeutically realistic definition of goals and of therapy sectors requires the skill, experience, and wisdom of the authors.

The reader who expects more than a collection of expertly conducted interviews performed by exceptionally skilled therapists using their particular methods will be disappointed. While an attempt is made to define sector psychotherapy accurately and as distinct from other approaches, the contents of this volume are not convincing that such a separate designation is justified. Equivalent therapeutic work, possibly less well schematized and formulated and not as well documented, is being performed in many

institutions. (French & Alexander, *Analytic Therapy*; Lidz & Fleck, *Psychosomatic Medicine*, 3: 103, 1950). However, as a presentation of psychoanalytically oriented therapeutic interviews and selected psychosomatic case material this volume is highly recommended.

A GUIDE TO PSYCHIATRIC BOOKS. (Second Revised Edition). By Karl A. Menninger, M. D. (New York: Grune & Stratton, 1956, 157 pp. \$4.75.)

In the 5 years since the publication of the first edition of *Guide To Psychiatric Books*, several related fields and subdisciplines in psychiatry have acquired substantial published material, which this second edition incorporates. Menninger has dropped his earlier method of starring preferred books, and re-arranged the table of contents to indicate the specialties that have risen in status during the past half decade.

The basic reading list for psychiatric residents is retained at the conclusion of the book, somewhat revised. A special reading list is offered for those interested in the interrelationships between religion and psychiatry.

Since this *Guide* is the only current comprehensive reading list in psychiatry published in book form, it will probably go into several editions. Only a person who has attempted to select the best that has been written in psychiatry would be in a position to quarrel with the selections here presented. Dropping the star-system in this edition further relieves the reviewer of the task of challenging marked preferences. All in all, the range of this guide is admirable, in view of its length (157 pp.). It is highly recommended.

A. C.

TRANVESTISM: MEN IN FEMALE DRESS. Edited by David O. Cauldwell, M. D. (New York: Sexology Corporation, 1956. \$3.00.)

This slim volume consists of 4 articles by medical sexologists, 4 by other writers and 11 autobiographic statements. Most of these have been reprinted from the journal, *Sexology*. It is pointed out that transvestism occurs more frequently in the male than in the female. The theories of causation which vary from physical to psychological, and mixtures in between are discussed. In classification the following types are mentioned: 1. heterosexual, 2. homosexual, 3. bisexual, 4. narcissistic and 5. asexual. The autobiographies illustrate clearly how often the patient's mother wanted a girl and literally raised her son to be one. Narcissistic, erotic, and compulsive features are also seen.

This book contributes little of value to the psychiatric profession as it is published for the general public. One feels that a well organized non-repetitious article in pamphlet form would have been more useful.

METHODISCHE PROBLEM DER KLINISCHEN PSYCHOTHERAPIE. By Dietrich Langen. (Stuttgart: Georg Thieme, Verlag, 1956.)

The term "clinical psychotherapy" as used by Langen in his book means psychotherapy in an inpatient setting as contrasted to the usual outpatient psychotherapy. The author, a disciple of E. Kretschmer in the department of psychiatry of Tübingen University, gives a comprehensive account of the methods used and the results achieved by him and his co-workers on a large number of neurotic and depressed patients. The sheltered climate of a hospital, the use of physical methods and group treatment in addition to individual psychotherapy make short-term treatment possible. Analysis of the actual conflict situation as well as of the personality structure marks the first step in the psychotherapeutic approach. On the basis of this analysis a formula is worked out which suggests the solution of the patient's actual problem. This formula is repeated to him in a hypnotic relaxation training program which follows largely the method described by I. H. Schultz. Group treatment is used for this relaxation training. Group discussions and psychodrama form other important parts of the group therapy. Subcoma insulin, fever and sleep treatment are used as adjuncts of the psychotherapeutic procedures. The technique of subcoma insulin therapy is described in detail. According to Langen, its value for a dynamically oriented psychotherapy is greater than that of the other physical methods because it facilitates drive processes and at the same time lowers the level of mental activity, thus leading to a dissociation most favorable for a dynamic understanding of the patient and his problems.

The book is written by a clinician experienced in clinical psychiatry as well as in psychotherapy. It should prove worthwhile reading for everybody interested in psychotherapeutic problems particularly in an inpatient setting.

DAS AUTOGENE TRAINING (KONZENTRATIVE SELBSTENTSPANNUNG) Versuch Einer Klinisch-Praktischen Darstellung. By Prof. J. H. Schultz. (9th Ed.) (Stuttgart: Georg Thieme Verlag, 1956. Price DM 29.-)

The ninth edition of this book differs very little from the previous one, reviewed in this journal (see Vol. 111, pp. 634, Feb., 1955).

A few elaborations were added to the management of the "first manoeuvre" ("Erstübung") in the exercise of "concentrative self relaxation." Also a few new data were inserted in the clinical and theoretical sections of this work. The more important ones deal with the changes in heat regulation as well as with shifts in the blood count and blood sugar content brought about by the physiological actions of this therapeutic technique.

ELECTRODIAGNOSIS AND ELECTROMYOGRAPHY. Edited by Sidney Licht. (New Haven: Elizabeth Licht, pp. 272, 1956. \$10.00)

In the introductory chapter the editor outlines the history of electrophysiology and its application to modern medicine. He traces the development over the last 200 years, and it is evident that most advances have been made in physiology laboratories and not in clinics. The physiology of muscle and nerve presents so many various aspects, involving so many different disciplines, that the wisdom of having different authors for every chapter is fully justified. Although each chapter deals with different aspects, there is some overlap, but this is an advantage since several points of view are expressed.

The electrophysiology of muscle has developed sporadically, usually with little or no contact with clinical medicine. Ever since the argument of Galvani and Volta as to the nature of "animal electricity" the theoretical aspect has been in advance of the clinical. This is well demonstrated in the present volume. The chapter on "The Basic Physiology of Nerve and Muscle" gives clear, straightforward descriptions and explanations. There is no question in the authors' minds of the value and accuracy of the information they are expounding. The sections dealing with the clinical aspects give the impression that they are striving hard to convince the reader of the value of the method. On the whole, the clinical chapters are rather disappointing, not because of the organization or presentation of the material, but because electromyography has relatively little to offer as a diagnostic or prognostic tool. The electromyography can demonstrate muscular spasm, denervation, reinnervation, and possibly gives some information about myopathies. But with the present state of knowledge it has not the clinical importance of the electrocardiogram or the electroencephalogram.

For any person having an interest in diseases of muscle, however, this is an excellent reference book. It contains in one volume papers on the major aspects of the physiology of nerve and muscle. These are well and clearly written. The clinical chapters define the method and with this guide even the beginner would have no difficulty in observing and obtaining suitable records.

This volume is the first of the projected series on physical medicine. If the editor can maintain the standard of the present volume, the series will become a standard reference.

RORSCHACH LOCATION AND SCORING MANUAL. By Leonard Small. (New York: Grune & Stratton, 1956. \$6.50.)

This manual fills the need of an ancillary text for the student of the Rorschach Test. In it the author has succeeded in presenting a graphic and systematic collection of data which will be of great value to both beginning students, as well as teachers of the fundamentals of the Rorschach Test.

One of the most important contributions of this manual is the systematic listing of the combined scoring experience of 18 eminent Rorschach experts including Rorschach, Oberholzer, Beck, Klopfer, Hertz, Loosli-Usteri, Rickers-Ovsiakina, and others. More than 6,000 responses are listed and scored as F+ or F— in addition to the scoring for area, determinant, and content. Thus, in addition to Beck's already published norms for F+, this manual now makes available an ancillary collection of F+ and F— responses gleaned from many experts of the Rorschach Test. Some criteria are now available for those responses not found in Beck's norms. A note of caution is needed in this respect to avoid confabulating F+ norms of the various Rorschach workers. For those who utilize the various levels of F+ percent according to Beck's norms, his list of F+ and F— responses can only be used in considering the level of form accuracy.

For the beginning student who is using Beck's introductory text (*Rorschach's Test, I: Basic Processes*, Grune & Stratton, New York, 1949.), this manual may be regarded as a companion handbook. It presents graphically each of Beck's location areas for each of the 10 test figures. These location charts permit quick location of the scoring areas and this is further expedited by a convenient thumb-index system included in the pagination of the text. Each response listed is scored for area, determinant, and content. Beck's Z scores are also conveniently listed for each of the 10 test figures. Popular responses are also listed, but include only those of Beck and other workers, which coincide with his list of P responses. Content categories and abbreviations are also those used by Beck.

In general, this manual enhances the didactic value of Beck's introductory text by presenting the mechanics of his system in an ingenious, graphic and convenient fashion. The listing of the scoring of each of the 6,000 or more responses does have some limited value. However, the author himself cautions the beginner "against using the manual to score responses in a mechanical and rigid manner. The material offered here is guide to the scoring experience of leading workers, but can not be a substitute for the careful inquiry which is the mainstay of Rorschach procedure." The scoring of other Rorschach workers was converted by the author to Beck's symbols for consistency. However, it would be best to regard such conversions as extending beyond the mere exchange of one symbol for an equivalent Beck symbol. For example, this is especially true if one attempts to equate the numerous combinations of symbols for shading responses as scored by others, to the 3 more succinct shading symbols of Beck (V, Y, T). In spite of this, the numerous examples may be regarded as guideposts for the beginning student's problems in scoring. At least, the scoring examples create an awareness of all the determinants possible in any responses which have to be decided upon by an adequate inquiry.

Bethesda, Md.

EUROPEAN AND BRITISH PSYCHIATRY¹T. FERGUSON RODGER²

The first point I wish to make to excuse my relative ignorance of developments on the continent of Europe and to emphasize my lack of qualifications to speak for my European colleagues is to point out that while you think of Europe and Britain as one, which is geographically correct, in psychiatry, as in other fields, both culturally and politically, the English Channel is a greater barrier than the Atlantic. Our isolation from the Continent and our closeness to you in America is not entirely explained by the absence of a language barrier between us; developments in American psychiatry always seem congenial to us because, I think, your problems, as well as your solutions, are very much the same as ours.

When we review the contribution of European psychiatry over the past 50 years, we do realise, however, that we, and I speak for both Britain and America, owe everything to Europe: our clinical classification, the psychobiological approach, psychoanalysis, all the physical treatments and electroencephalography. We are now being offered existentialism, applied to psychotherapy, and we are both showing the same resistance to accepting it.

I believe, although it is perhaps only an impression which would have to be justified by a study of the literature, that we tend to accept developments from America rather than direct from Europe. My knowledge of European psychiatry is, I confess, very imperfect and I am aware only of those features which have recently made some kind of impression on British psychiatry. In the case of German psychiatry we are still a little estranged because of the war: we cannot altogether forget that German psychiatry, having shed psychoanalysis, was able, with seeming ease, to adjust its beliefs so that they became compatible with Nazi myths and

theories. Typologies lent support to racial prejudice and phenomenology was less critical of unreason than a dynamically oriented psychiatry might have been.

Perhaps the unity of British and American psychiatry is best explained by the fact that in our two countries, but not on the Continent, the psychobiological doctrine of Adolf Meyer came to be widely accepted. Macfie Campbell and David Henderson left Edinburgh to sit at his feet at Ward's Island. Henderson returned to become the leading figure in British psychiatry and wrote a textbook with Gillespie which became our standard work, effectively superseding all others within a few years of its publication in 1927. As a result my own generation tended to make the pilgrimage to Baltimore for our postgraduate training.

Although Henderson and Gillespie's text was hardly a full statement of psychobiological doctrine, it conveyed its essence and gave an admirable grounding in a dynamic approach to case-history taking and therapy. It was in this way that the psychobiological point of view sank in and became implicit in British psychiatry although the debt we owe to Adolf Meyer is seldom realised and even less frequently acknowledged.

This acceptance of an essentially dynamic viewpoint has created a soil on the whole more favourable to psychoanalysis than to phenomenology. It is on this background that the significance of the publication of a textbook of Clinical Psychiatry by Mayer-Gross and others, which is phenomenological in its outlook, has to be judged. Although the book has puzzled American reviewers who see it as some kind of throwback to a primitive phase of psychiatry, there are many psychiatrists in Britain who would regard it as a salutary return to careful clinical appraisal on a symptomatological level. This kind of approach is fostered by an interest in physical treatments. The mental hospital psychiatrist whose main problem is to decide which physical treatment he will use finds help and guidance in phenomenology although the same psychiatrist is likely also to be inter-

¹ Read at the Symposium, "Perspectives on International Psychiatry," at the 114th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² Address: 25 Campbell Drive, Bearsden, Glasgow, Scotland.

ested in psychoanalysis and the help it can give him in dealing with his psychoneurotic patients in the outpatient department.

Before I discuss British psychiatry further, I should turn to some consideration of the various points of view of which we have become aware in Europe during the past 10 years. It seems to us that in most of the European countries, the main emphasis is on physical treatment and in research based on biochemical or neurophysiological considerations. France has given us chlorpromazine; in recent years Switzerland has given us L.S.D. and the model psychosis as a field for research. In France the clinical approach emphasises careful case studies at the phenomenological level and, as I have said, many British psychiatrists would regard this emphasis as being salutary because careful case studies have been neglected in many other countries. Henry Ey has developed an organic-dynamic approach which has been called neo-Jacksonianism. Based on Hughlings Jackson's principles of evolution and dissolution of levels, his contribution is considered very significant by some British psychiatrists.

In Germany the impression one gets is that psychotherapy is practised on a rather superficial level and even on authoritarian lines but we are prepared to believe that it may be effective for all that. Our cultural differences explain our lack of interest.

But many German and Swiss psychiatrists have been influenced by the existentialist philosophy of Jaspers, which is based on Kierkegaard and Heidegger, and the revival of interest which is taking place in Germany in psychoanalysis tends to be combined with the existential analytic approach propounded by Binswanger. In Austria, Frankl of Vienna has promulgated his extended psychotherapeutic approach combining ordinary psychotherapy with logotherapy, which emphasises the importance of human responsibility. Frankl's views have attracted attention in Britain. He recognises three principles of importance to psychotherapy, the will-to-pleasure characteristic of psychoanalysis, the will-to-power of individual psychology, and what he would call the will-to-meaning. He regards the will-to-meaning as "that which most deeply inspires and pervades man"; "the innate, albeit often unconscious and

sometimes even repressed, desire to give as much meaning as possible to one's life, to realise as many values as possible." "Psychotherapy," he says, "would turn this will-to-meaning . . . into a human frailty, a complex, or something of the kind."

This aspect of existence, the will-to-meaning, according to Frankl's view, lies outside psychotherapy, as ordinarily understood, in the spiritual domain. He defines logotherapy as a psychotherapy which not only recognises the spiritual, but starts from the spiritual. He believes that just as sexual frustration can lead to neurosis, so also can frustration of the will-to-meaning lead to an existential neurosis. He traces the modern epidemic of neurosis to man's fear of responsibility and his weariness with the spiritual. He therefore recognises existential neurosis as a clinical entity which arises out of philosophical perplexity and the failure to find an adequate meaning for life. He and workers in Kretschmer's clinic categorise 12% of their neuroses as being of this kind.

In very recent times there has been more interest in existentialism in Britain, for example one of my own staff who is psychoanalytically orientated takes part in an informal discussion group formed by members of the Faculty of Divinity and some psychiatrists, which meets regularly to discuss these new ideas. It is possible that similar groups, not, as yet, expressing themselves in print, are being set up in other parts of the country. It is, perhaps, not without significance that the annual conference of the National Association for Mental Health, held in Britain in the spring of 1956, had as its theme Personal Responsibility in Mental Health, and the views expressed by the various speakers showed the same kind of preoccupation with the significance of responsibility in relation to mental health as their European counterparts, although I doubt if there is any direct link between them, merely a growing consciousness of the effects of a dissolution of value systems as a result of war and the upheaval in European societies. In part these trends emerge out of the feeling that with neurosis increasing rapidly in Western countries it is too much to expect psychotherapy to cure all our psychic troubles and restore human dignity. After years of propaganda

in which we advocated the importance of psychotherapy we have come to consider that perhaps psychiatry and psychotherapy have been oversold and that, in the long run, we shall never be able to overtake, unaided, the enormous task which confronts us. This point of view has even been expressed in the correspondence columns of the *Manchester Guardian* (April, 1956) where doctors have expressed the dilemma in which they find themselves; they are seeing more and more patients suffering from neurosis and they can choose two ways in which to treat them. They can either use the various chemical compounds urged on them by the manufacturers which depress or excite the C.N.S., or, as most of them believe is the right course, they can attempt to treat their patients as human beings and try to help them by sympathetic understanding. Those who endeavour to help their patients by the second method find themselves too much involved. There is plenty of willingness to help and no great reluctance to recognise neurosis and to treat it as such but once the doctor begins to adopt this attitude to his patients, his responsibilities enlarge and can never be defined in terms of his medical duties. Doctors, in other words, are beginning to wonder whether, when a patient comes with a problem about his marriage or his career, he is not going beyond what can reasonably be demanded from his doctor. One effect of the National Health Service has been to extend the patient's concept of the doctor's responsibility. On the whole doctors welcome this manifestation of a closer emotional relationship between doctor and patient, so different from what had been expected, in some quarters, from the National Health Service. But now, faced with apparently unlimited medical responsibility, they are asking what the community can do to share the burden which the doctor at present carries on his own.

For example, The College of General Practitioners in Scotland has expressed its interest in investigating this problem in the form of an enquiry into the prevalence of neurosis in practice to take into account such personal factors as personality, training and experience as determinants of the medical relationship which allows the patient to express his problems to his practitioner.

From the side of the church, in Scotland at least, there is a definite desire to be helpful through industrial and hospital chaplaincies and expanding objectives in pastoral care. They are asking for cooperation on the part of teaching psychiatric units to give courses for clergymen, not to help them to become psychotherapists but to give them an increased insight into how to handle human problems falling within their own sphere. It is unlikely that, in Britain, psychiatrists will extend their psychotherapy to include the spiritual side of their patients' problems as Frankl's approach would suggest, but they will expect clergymen to play an increasing part in the mental health field.

Those with a key position in the community are becoming increasingly aware of their responsibilities in regard to mental health. An extramural course on mental health at the University of Glasgow, each year attracted more nurses, teachers, local government officials and the like until the success of the course proved an embarrassment to us because of the numbers. Mental hospitals have numerous offers by laymen who wish to do something on a voluntary basis for mental patients and very successful committees have been created in the mental hospitals who visit and take responsibility for some aspect of the patient's welfare. Numerous other organisations have sprung up spontaneously throughout the country to care for sick and disabled persons and their influence has been wholly good. They are not pressure groups but provide such auxiliary services for patients and their relatives as they find within their competence.

It is recognised that statutory services for the care and aftercare of the mentally disabled are required and provision is made for them. I, personally, am not satisfied that we have found the correct pattern for these services and, at least in Scotland, there is an unexpressed mood to await developments before formulating the kind of service which will be most effective. Local government in Glasgow has expressed its need to learn by establishing an informal link with the University for mutual study of social factors in mental health. A link of this kind is neither traditional nor envisaged in any statutory enactment. It arises out of the recognition that public welfare devoted to the satisfac-

tion of material needs and to ensuring that no sick person goes untreated only goes so far and there is a need to tackle problems in the community of a new kind. The new housing estates provide satisfactory living conditions in terms of accommodation and hygiene but produce isolation and dissolution of previously healthy social groupings.

In these ways psychiatrists are being brought to face the social problems which lie behind their practice. Mental hygiene for the psychiatrist becomes a matter of aiding and advising on developments which arise spontaneously elsewhere.

Psychiatrists in Britain nowadays almost always have a part to play in a general hospital through the setting up of outpatient clinics in general hospitals staffed by mental hospital psychiatrists. A process of mutual learning and understanding is taking place whereby the general physician, the surgeon and the psychiatrist cooperate in the investigation of their cases. The fact that psychiatry has been invested, over a comparatively short space of time, with heavy responsibilities by an all-inclusive health service, renders psychiatrists less liable to involve themselves in responsibilities for treatment in cases where other specialities have as yet equal or superior claims. The position therefore is, that psychiatrists are co-operating with their colleagues in research in dermatology, general medicine and other fields, stressing etiology rather than therapy. The fact that we are thus absolved from the criticisms that might arise from premature claims in the field of psychotherapy has helped in creating a harmonious relationship with our colleagues. This kind of psychosomatic approach has the virtue of avoiding the one-sidedness of some formulations which proffer a ready-made holistic psychological conception which cannot always be readily accepted by physicians who are only too well aware of their own side of the story.

In our own hospital department mutual helpfulness has resulted in research projects into asthma, coronary thrombosis, ulcerative colitis and phthisis.

It is in this field of psychosomatic research that the liaison between continental and British psychiatrists is greatest. The work which is being done at Amsterdam and

Heidelberg has attracted a great deal of interest on the part of British workers. The editorial and advisory boards of the new *Journal of Psychosomatic Research* has members in Amsterdam, Rome, Stockholm, Madrid and Copenhagen, and British psychiatrists have been meeting their continental colleagues at an International Conference on Psychosomatic Research which was held in Amsterdam in April, 1956.

Sweden's main contribution, as it appears to us in Britain, is in the field of studies in heredity. It is perhaps significant that Germany, which led the way in this field before the war, seems to have given it up perhaps because it had become discredited through being used by the Nazis. The rightful heirs of that school of psychiatry are now Franz Kallman in New York and Eliot Slater in London.

The epidemiological surveys of the Scandinavian countries which are chiefly concerned with isolated rural populations are interesting methodologically and therefore have a basic scientific value but, since they are not dealing with the pressing problems of industrialised and urbanised communities, they seem rather remote from our concerns.

Here our interests are very much the same as yours because in common with you we are dealing with a highly industrialised society. Like you we are trying to develop a social psychiatry and in this there are determinants peculiar to our own development.

Since 1948 when the National Health Service came into existence, the development of psychiatry and the Mental Health Services can only be understood in relation to the new organisation of the Social Services. The idea of a welfare state, while it may not be politically acceptable to our critics, is now an important part of the British way of life. It would, of course, be untrue to say that doctors are wholly satisfied with the new regime but it is true that the majority accept it wholeheartedly and their frustration chiefly derives from the fact that the economic position of the country does not allow the further developments which everyone realises are desirable.

Psychiatry has gained by the National Health Service because mental health has now been given equal status to physical

health. The realisation by hospital authorities and the public that mental hospitals and psychiatric units had been given an inferior status in the past has created a loudly expressed demand in parliament and the press for improvements in hospital buildings, furnishings and diet as well as greater attention to research in mental health. This has happened elsewhere too, here in America, for example, through the care you have given to your veterans, but in Britain it is through the National Health Service that such changes are taking place.

The patient, and that is everyone in the community, has now the right to every kind of treatment and this has meant an enormously increased demand for psychiatric treatment. Ninety-eight percent of psychiatric patients under statutory care are in hospitals financed by the state.

The very great increase in admissions to mental hospitals, which began at the outbreak of the war when electroplexy was introduced, was accelerated after the war with the inception of the Health Service. In Scotland, for example, with a population of 5 million, the rate of all admissions to mental hospitals in the 5 years up to 1942 was steady at about .73 per thousand of the population per annum; by 1947 this figure had increased to 1 per thousand and in 1955 it was 1.76 per thousand—an increase of nearly two-and-a-half times in 13 years. This very great increase was due entirely to the rise in voluntary admissions over this period from approximately a total of 1300 in 1942 to 6,600 in 1955. The number of certified admissions in fact declined.

Patients, on the average, now spend only 1.9 months in the mental hospital and nearly three-quarters of all new patients are discharged within a year. It is a remarkable fact that this phenomenal increase in admissions took place with no significant expansion in the number of beds and, at first, with no great increase in the number of medical staff. Since 1948, however, there has been a steady increase in the number of psychiatrists employed throughout the country. Until 1954 the increase was proportionate to that which was occurring in other specialties but, in that year, the number of psychiatrists in training at the senior level had outstripped those in training for other specialties.

The provision for outpatient clinics has been greatly extended. Before 1948 only a few mental hospitals had responsibilities for outpatient clinics in general hospitals. Now the average hospital in England and Wales is responsible for about three such outpatient clinics.

The extension of the mental hospital psychiatrist's responsibilities to the outpatient clinic has led to a reorientation of his view of the mental hospital. While he has been spending a great deal of time with outpatients and has been handling a vastly increased number of patients seeking early treatment, this has not been at the expense of the chronic patients. On the contrary, the more helpful attitude which he is able to take regarding his newly admitted patients has led him to ask what more he can do for his chronic patients. There has been much more attention given to recreational and occupational activities in the hospital. At Banstead Hospital a Medical Research Council team has been supervising an experiment to create a factory within the hospital providing paid employment for the patients with, according to the first reports, remarkably encouraging results. Others have been discovering the value to the chronic patient of increased interpersonal relationships. In Glasgow, an experiment in group therapy of chronic schizophrenia gave promising results and indicated ways in which the therapeutic potential of the nurse and the mental hospital as a community could be increased.

Some of the enthusiasts for this new approach to rehabilitation already envisage their hospitals being emptied of all but a small residue of their chronic patients. They want no more hospital accommodation to be built until the effect of these measures has been fully worked out. The whole system of institutionalisation and alienation is suspect. The view is taken that it may produce more problems than the disease itself. This is one reason why there has been a very great interest in Querido's experiments in domiciliary care of psychiatric patients in Amsterdam.

Under the Health Service domiciliary consultations have increased by almost 100% in the 4 years between 1950 and 1954 and most psychiatrists would like to see much more attention being given to this aspect of the

Service. The need is for auxiliary workers and there is a great deal of discussion about the potential role of the public health nurse in the field of mental health. Day hospitals are also popular as a means of avoiding hospitalisation—there are now 16 in England and Wales dealing with psychiatric patients.

As you can see, psychiatry in Britain is changing its shape rapidly; it is acquiring a wider social orientation. While the service is still centered on the mental hospital the activities of its staff extend far beyond its walls.

Mental hospital psychiatrists now care for thousands of outpatients suffering from psychoneurosis. This responsibility is somehow being discharged although only a very small minority of the psychiatrists who undertake it have had any formal training in psychotherapeutic techniques. Most psychoanalysts are still in full-time private practice and there are only two outside London with responsibilities for teaching undergraduates or graduates. British psychiatrists are, on the whole, sympathetic to analysis but the analysts have played, up to the present time, a very minor role in the significant developments which are taking place in British psychiatry.

Obviously more attention will have to be paid to training psychiatrists in psychotherapy. At present there is only one Institute of Psychoanalysis in Britain providing intensive training, including personal analysis, and this has so far turned out only a few psychoanalysts who are interested in the general field of psychiatry. All we can do meantime in Scotland and the provinces is to use the few analysts who are prepared to pull up their roots in London, and act as supervisors of psychiatrists in training. Dr. Freeman, who came to my department 4 years ago as lecturer in psychotherapy in the university has been very helpful but he is the only analyst so employed outside of London. Most

university professors, of whom there are now 9, with 2 more to be appointed this summer, are turning this problem over in their minds and trying to find some kind of solution but it is unfortunate that the situation in regard to the contribution which psychoanalysis could make should be so unpromising.

While most psychiatrists are doing psychotherapy because they are committed to satisfying a demand and are prepared to honour their commitments as best they can, the whole question of the value of psychotherapy is still unresolved. Eysenck has issued a challenge. He asks for a demonstration of the effectiveness of psychotherapy. This is the kind of challenge which cannot be ignored in Britain where national resources are involved. So far psychiatrists have been too busy doing psychotherapy to take time off to examine what they are doing and, moreover, few of them would be satisfied by a formal experiment purporting to test its value. The fact is that the demand is there and the service has to be given.

One last remark, as you can see there is some kind of determination to be open-minded about future developments. Psychoanalysis is tolerantly regarded but by no means supreme, in the field of psychiatric thought. As on the Continent, there is a desire to see psychoanalysis extend its concepts, to become more biological on the one hand and at the same time to comprehend more of man's nature on the other. On the biological side, Lorenz and Tinbergen have had a vital impact, although as Kortlandt has pointed out their views could be greatly widened if they could assimilate the contribution of psychoanalysis.

This relationship between ethology and psychoanalysis is the development which I personally would single out as being the most significant.

INTERNATIONAL PSYCHIATRY¹

IAGO GALDSTON, M.D.²

There is an embarrassing vastness to the name of international psychiatry. One could almost treat of anything and still be talking in the subject. Under the circumstances, it seems best to approach it at its simplest level. Thus, suppose we were to treat of surgery and not of psychiatry, then what would we say about international surgery? I suspect that all of us would agree that surgery is surgery the world over. Such differences as may exist between the surgery of one country and that of another would be reflective of advancement or retardation, that is, some countries would be technologically a bit ahead and others a bit behind, but they would all be traveling the same road. One could then affirm, without fear of contradiction, that surgery is one and the same the world over—that it is in other words truly international. But is this equally true in psychiatry? Let us take a look at a singular example. Let us look at, say, an American worker, and at his Russian counterpart. Let us assume that each has suffered, say, a compound fracture of the humerus. I am quite certain that in each instance the procedure followed in the treatment of the fracture would be, if not identical, certainly close enough to be equivalents. In other words, the American worker in America and the Russian worker in Russia could be interchanged in the locus of treatment, and yet come out having had pretty much the same experience. But now let us assume that instead of having suffered a fracture we are confronted with a Russian and an American, each of whom is suffering from some psychiatric illness—say a hand-washing compulsion. In such a case, one could be sure that the treatment of the Russian and that of his American counterpart would be quite different. The Russian therapist, treating the Russian, would be oriented in Pavlovian

psychiatry, and would be indifferent to and indeed even antagonistic to psychoanalysis and to all forms and schools of depth psychiatry. The American psychiatrist, on the other hand, while perhaps not too well informed on the subtleties of the conditioned reflex, would not be overtly antagonistic to them. His therapeutic accents and emphasis however would be radically different from those of his Russian counterpart. To summate this—the Russian surgeon would closely resemble the American surgeon. But such would not be the case with the Russian psychiatrist and his American counterpart. Let me paraphrase it still another way—there is an international surgery, but only a *national* psychiatry.

One might easily be tempted to believe that the instance cited is loaded, that the example is unique—with Russia at one pole and the United States at the other. Or one might even assume that the difference is not really Russian, but merely Communist in character.

This assumption however, would be not only erroneous but also beside the point. Pavlov was a Russian and really never a Communist and Russian psychiatry was always different from European psychiatry (Korsakov—Bechterov), just as Russian literature and Russian drama differed from that of Europe.

The fact is that psychiatry is *nationalist* in character not only for Russia but for most countries and for most nations. In that respect it is unique among the biological disciplines and specialties!

What evidence can we muster for this affirmation? I think the data of history will do very well. Thus I am sure it was no accident that both Mesmer and Freud were not only citizens of the same country, Austria, but also of the same city—Vienna. Nor is it a negligible fact that Romantic Medicine had its roots and its broadest field of exercise in the Germanic countries. Among the great authors of the Romantic Period are to be found the anticipators and the forerunners

¹ Presented at the 9th Annual Institute in Psychiatry and Neurology, VA Hospital, North Little Rock, Ark., February 28, 1957.

² Chairman, Committee on International Relations, The American Psychiatric Association. Address: 2 East 103rd St., New York 29, N. Y.

of modern depth psychology. These are to be found no less among the novelists and poets—Novalis, Tieck, Schlegel, Chamisso, and Uhland, than among its scientists—Carus, Schelling, Oken, Schubert. Carus had fathomed the role of the unconscious in the operations of the psyche some 60 years before Freud, and Schubert wrote a work on dreams which is in some respects superior to Freud's classic study. Austro-Germanic psychiatry stands in marked contrast to that of France, and of most of the Latin countries. In a measure it was cultivated in protest to the rationalist-materialist-mechanist viewpoint, developed by the outstanding French scientists during the Age of Enlightenment. French psychiatry took its line of departure from Descartes, and down to the time of Pierre Janet has been essentially, and almost exclusively Cartesian, that is *materialist* and *mechanist*.

The fame of French psychiatry derives from its liberal, humanitarian, custodial treatment of the insane. Its psychiatry, however, has practically always been mechanistic. Janet, who perhaps better than anyone else in modern times, has given us a definitive nosography of the neuroses, and who thereby came so very close to Freud's ideas that some have suspected Freud of plagiarism, was yet a mechanistic psychiatrist, quite in the Cartesian tradition. Neurasthenia, which to Janet was the critical etiological factor in mental disease, and particularly in the neuroses, is primarily an energy concept. The neurasthenic is one who is weak or weakened in the operations of his nervous system. Neurasthenia, incidentally, was a psychiatric concept also much favored by American psychiatrists in the early part of this century, notably by Boris Sidis.

French psychiatry and Austro-Germanic psychiatry are two outstanding examples of what can with warrant be termed—national psychiatries. But English, Italian, Swiss, and even American psychiatry have each their distinctive national accents. The English have given rise to no definitive "schools of psychiatry" but in psychiatric practice they have been and continue to be pioneers in the "custodial treatment" of the mentally sick. I call to your attention the noteworthy work of T. P. Rees.

The French, following on the revolutionary and dramatic achievements of Pinel, gained a reputation for the humane treatment of the insane, but it was, I am sure, the English who actually and consistently achieved the most in this sphere. This is quite understandable, for it is in consonance with the spirit and tradition of British social justice and British social reform. Swiss psychiatry has, it seems to me, always been rather heavily freighted with moral and religious considerations. Jung, of course, may be cited in witness, but the characteristic antedates Jung, and is reflected, for example, in Maeder's work, as well as in that of Forel.

Italian psychiatry is difficult to characterize, for it shares in a large measure the imprint of French psychiatry; it is in other words permeated with the philosophy of Cartesianism. One thing, however, is noteworthy. Italian psychiatry as Italian medicine in general is rich in *instrumentations* and in instrumental procedures. The Italians have been good technicians and medicine entire has profited by their skills. One can think at random of Galileo, Sanctorio, Borrelli, Volta, Forlanini, Cerletti—men who have enriched the practice and science of medicine with the products of their inventive genius. Electroshock therapy and electro-narcosis are Italian contributions to the physical modalities of psychotherapy (Cerletti and Bini, 1938).

American psychiatry, by which I intend psychiatry in the United States, is essentially eclectic, and if there is anything distinctively national about our psychiatry it is the facility with which we accept and make our own the scientific contributions of other peoples and of other nations.

In psychiatry we are not chauvinists. It is indeed noteworthy how very few of the psychiatric formulations, academic or otherwise, and how very few of the psychiatric diagnostic or therapeutic procedures we utilize are truly native in origin. Our contributions in psychiatry are less of an inventive nature and more of an elaborative character. We "take over and develop," sometimes, as in the case of behaviorism, with rather unhappy results. In all of this I am not unmindful of Adolf Meyer's contributions, those of Sul-

livan, and those of Trigant Burrow, three of America's most original psychiatric theoreticians. Trigant Burrow, incidentally, is all-too-little known and appreciated. However, despite this cluster of brilliant minds, and others besides whom I have not named, American psychiatry is much more eclectic and integrative than original.

This brings me to something which I must hasten to express. Generalizations concerning the psychiatry of a country are as subject to contradiction and exception as is any generalization about a *people*. We say Norwegians are tall, blond, and blue-eyed, while Italians are short, dark, and brown-eyed. But there are some short Norwegians, and in Northern Italy there are quite a number of tall, blond Italians. And yet despite these exceptions, the generalizations still *are valid as generalizations*.

Scanning the distinguishing characteristics of nationalist psychiatry, I could not but also recall that Mesmer had his greatest triumph not in Vienna, nor even in Austria, but in Paris, and yet it was the Commission of the French Academy whose membership included our own illustrious Benjamin Franklin, which, so to say, gave the "*coup de grace*" to Mesmerism in France, with what we now cannot but esteem as the fatuous judgment—"*l'imagination fait tout, le magnétisme nul*." England was in effect the land wherein Mesmerism found its most devoted and intransigent defenders and theoreticians, in Braid, and Ellistson.

Charcot, Bernheim, and Liébeault are the links whereby Mesmerism, transmuted into hypnotism and suggestion, reach to Freud, again on French soil. Nor can we overlook the fact that psychoanalysis found its first "academic" recognition not in Austria but in Switzerland, at the Berhölzli in Zurich, and that the United States more than any other country has proved hospitable to the "Viennese—Romantic." It was an event of heroic proportions when, in 1909, Stanley Hall invited Freud to come to America to expound his psychological theories, and James Jackson Putnam, then in his sixties, became a student and advocate of psychoanalysis.

I have set in opposition the Austro-Germanic and the French schools of psychiatry, yet one could question whether any French

admirer of Descartes could out-vigor in his Cartesianism, that is, in his determinist and mechanistic interpretations of the human brain and of its operations, Freud's own teacher, Theodor Meynert. Add to Meynert, DeBois Reymond and von Helmholtz, and you have a masterful contingent of Cartesians right in the very heart of the Germanic realm.

All this would then appear to invalidate any assumption of a nationalist psychiatry. But in effect it doesn't and cannot—just why, I'll demonstrate later.

The exceptions I have cited, and I could well have increased their number tenfold, only prove that every valid generalization has its exceptions which while true enough do not singly or collectively invalidate the generalization. Or to paraphrase it, homogeneity is a statistical preponderance, not the highest state of uniformity. The Norwegians really are tall, blond, and blue-eyed, even though some Norwegians are otherwise.

Now then, you might properly ask, suppose we grant you all this, suppose we grant you that regional psychiatry is nationalist in character, what of it?

The answer is that in this concurrence we have the validation of a most interesting and most provocative issue, namely, *Why of all the medicobiological disciplines is psychiatry the only one that is nationalist in character, while all others, say surgery or endocrinology, or immunology, are global, universalistic, or, as we have affirmed it, international in character.* The answer to this is as simple as it is direct, and, as it is exquisitely significant. It amounts to this: in all other departments of medicine the physician intercedes between man and nature, and, of course nature is the same the world over. In psychiatry however, the physician intercedes between, not only man and nature, but most often and mainly, between man and society, and society, that is the social organism, its structure, operations, exactions, etc., quite unlike nature's, is *not* the same the world over. Society frequently changes in the most astonishing ways "*at the national border.*"

Psychiatry, though essentially a biological science, must perforce take into account and be responsive to the societal and cultural field forces in which its subjects operate.

That is why psychiatry takes on a nationalist complexion. For psychiatry is in effect an anthropological science, superstructured on the elementary sciences of neuro-anatomy, neuro-physiology, and functional psychology. Mankind, hedged in by the universal and omnipresent demands of nature, has, during the 500,000 years of his being on earth experimented with, and has cultivated a variety of ways to meet them, and these he has formulated and sanctioned in a variety of ethical, cultural, economic, aesthetic, and moral patterns, all of which are reflected in his singular societal group pattern.

Hunger is hunger, the world over. But how man satisfies his hunger, be it for food, sex, property, or power, differs the world over. Psychiatry is involved not only in the anatomy and physiology of hunger, but even more, in the societal group patterns, the mores and taboos for satisfying hunger. That is why psychiatry is, initially nationalist in character. For nations do have a predominant and characteristic group pattern for ethical, cultural, economic, and moral operations.

Salvador de Madariaga, in his stimulating book *Englishmen, Frenchmen, Spaniards* (Oxford Press, 1920), makes these pertinent comments.

There is such a thing as national character. Opinions may differ as to the influences which create or alter it. Race, climate, economic conditions, may enter for a greater or lesser part in its inception and development. But the fact is there and stares us in the face. History, geography, religion, language, even the common will are not enough to define a nation. A nation is a fact of psychology. It is that which is *natural* or *native* in it which gives its force to the word *nation*. A nation is a character. (p. 41 *op cit.*)

To affirm, and to concur, as I believe we must, that "A nation is a fact of psychology," and that "A nation is a character," is to do more than to second and endorse the apt phrases of an ingenious social observer. It is, as a matter of fact, to take on the commitments of some very pertinent implications. It is indeed to acknowledge that psychiatry, though rooted in biology, transcends it, reaching into the outstretching terrains of social anthropology and ethnology. Thus we cannot and may not expect to find an answer in the data of neuro-anatomy and neuro-physiology, reined though they be to the ul-

mate, to the problems that derive from value judgments, life goals, ambitions, ideals, or from conscience and guilt. These, in the last analysis, are societal rather than simply biological quanta. Likewise, these in the last analysis give meaning to the affirmation that "A nation is a fact of psychology," "A nation is a character."

There is a converse implication: it may be that the problems themselves, those which psychiatry confronts, may not be biologically solvable, even with the aid of the most sovereign tranquilizers, but may be amenable to solution only as value judgments, life goals, ambitions, ideals, and guilt are modified and made more reconcilable with human capacities, and with the potentialities of reality.

Recently, I was privileged to take part in a conference of very learned professors (I was the mute and generously tolerated outsider), who ventured to question the assumed superiority of the Western world's concept and ideal of individualism, seeing that this ideal was shared neither by the Chinese, the Indians, nor the Russians. The crucial issue however, turned out to be not the superiority of the Western world's idea of individualism, but rather, whether in effect it was an existing reality, and not merely a figment of the imagination. All this, however, has taken me far afield, and you might properly ask—what has it to do with International Psychiatry. Indeed, you might go further and affirm something of this order: granted that psychiatry carries the complexion of its national locus, I, myself, as a psychiatrist, am after all national rather than international: is it not then quite sufficient for me to be acquainted with, and facile with, my own native psychiatry? Must I also be informed on, and at ease with, Russian Pavlovianism, Austrian Neotranscendentalism, French Existentialist psychiatry? Obviously, there is no *must* in the situation, nor in my argument. The compulsion or *must*, to *appreciate international psychiatry*, derives, if at all, from one's own professional body image, or if you wish, from one's ego ideal. Spoken plainly it means "it all depends on how sophisticated you aim to be in your professional orientation." But in truth there is more to it.

There is an ancient saying "I fear the man

of one book." I would paraphrase this to read "I fear the monolithic psychiatrist!" I fear the man of one book, the orthodox devotee of the one school, the so-called elect among the elect. Historically there was justification for partisanship. The pioneer must perforce be the passionate protagonist. But we are now far beyond the pioneering stage in psychiatry. The affiliation suffix *ian* must currently be deemed the symbol of an arrested fixation.

In psychiatry it is incumbent upon us to *recognize* national accents, but only within the purview of an international encompassment. I am sure this is none-too-clear, but then the issue itself is complicated and obscure. Let me try to make it a bit clearer. In the different nationalist cultures it was not different species of men that came under scrutiny, but rather the same men, under different scrutinies. The Russian isn't really different from the New Zealander or the American. It is the "emphasis," as the Frenchman said, that differs. There is no economic man, distinct, say, from the religious man, or from the biological man, or from the social man. There is but one man, to be studied from many angles.

Much of psychiatry, propounded on a nationalist level, and espoused by the so-called singular schools of psychiatry, is, however, single-faceted, not all-inclusive but rather parochial. Thus we encounter schools that accent "the instinctual man," or "the neurological man," or "the spiritual man," and so on. The overriding evidence, however, is that man is *none of these, singly, but all of them, collectively*. Man is "instinctual," "economic," "neurologic," "spiritual," and, much more besides.

I have drawn great encouragement of late from the criticisms leveled, chiefly by the younger men, against the orthodox positions of the older schools, which are seemingly indifferent to, or ignorant of, the economic, social, cultural, and religious factors that enter into and affect mental and emotional health and stability. They ask, for example, what of the minority group individual who finds himself in the midst of an inimical majority. What order of normalcy can you expect from him, and may not his "abnormal"

reaction be situationally quite normal? I have been much stimulated by the resurgent interest among psychiatrists in the role of religion in the emotional life of the individual. There is a most praiseworthy concern now emerging with the *family* as the matrix setting of the individual, and it is encouraging that even among the orthodox analysts some have come to recognize the difficulty, nay at times the impossibility, of dealing with one partner in a marriage to the exclusion of the other, or with one member of a family group to the exclusion of the other crucial members of the family group. What I am saying then is that an appreciation of the varied and different approaches to man reflected in the historical psychiatry of different nations, and integrated in a global survey of psychiatry, will afford us a better balanced and more comprehensive understanding of man psychological.

We need to cultivate such a balanced and comprehensive understanding of man psychological, in order that we might be better, *i.e.*, more effective psychotherapists, and also that as educated men in positions of power and prestige, we might help mankind to wrestle more effectively with the enormous problems confronting us. We in the United States are in particular need for a comprehensive understanding of man psychological, for we are, ourselves, an international nation—that is, a nation more *compounded* than *amalgamated*, out of many nationalities. I grant that even as psychiatrists we cannot be all things to all men, but we can and must seek to understand more things about more humans, for in essence this is requisite to our function.

We once entertained in this land of ours the fiction of a melting pot. The crude ores of all our immigrant peoples were to be smelted into the prototype of Homo Americanus. But it was never effected: and isn't ever likely to be, and thank the Lord for that. Nor, looking forward, does it seem likely that this world, becoming *one world*, will be rendered as of one world.

Before World War I, at the time when the melting pot idea was so common, we in America also believed that we were at the head of the procession marching on the long

road from barbarism to democracy. We looked upon the backward nations, *i.e.*, those ruled by kings and emperors, those without bath tubs, refrigerators, automobiles, votes for women, and other "civilized" appurtenances, as stragglers on the highway of civilization, late to get started and slow to move on, but likely, with our good example before them, to get going, and in time perhaps even to catch up. Without affirming it in so many words, we assumed that America forecast the pattern of things to come for all peoples and all nations. If you will trouble to study Woodrow Wilson's political philosophy and his 14 points, you will perceive how much

we considered ourselves the pattern for all men.

Two world wars and the challenge of two non-democratic philosophies of government—fascism and communism—(I cannot count Nazism as a philosophy but only as an epidemic madness)—have sobered us in our expectations, and have prompted us to question our assumptions.

We are beginning to suspect that there may be *not one*, but many ways to live life, that *I* for example might prefer individualism, but that collectivism is preferred by others and may even be more—in this complexity—suitable to their needs.

AMERICAN PSYCHIATRY¹

JOHN C. WHITEHORN, M.D.²

To give a brief yet meaningful view of American psychiatry—that is the task required of me at this moment. To make it brief means to omit much; to make it meaningful means to express (or to imply) some interpretations. Selection and interpretation inevitably produce some distortion. I hope that the distortions involved in my brief sketch will not produce an unjust caricature, or any unjustified eulogy, of the professional work and aims of American psychiatrists—a professional group approaching ten thousand in number, with widely diversified interests, working in a general population which regards their efforts with unprecedented interest and which grants them an unaccustomed measure of acceptance. This situation astonishes the rest of the world—and it is also somewhat confusing to us.

It is perhaps fortunate that I must present this view of American psychiatry in the presence of a considerable and important segment of the American psychiatric profession, competent to set me right in any serious misstatement, but, I hope, sufficiently kind to overlook minor lapses.

The historical background of American psychiatry has been the humanitarian but medically professionalized care and treatment of the insane; but a very significant recent development has been the increasing attention and effort devoted to the problems of life stress and to the treatment and prevention of neurotic discomforts and disabilities.

Quasi-technical psychiatric terms like "personality," "attitudes," "reactions," "complexes," "defense mechanisms," etc., have gained wide popular usage and the climate of opinion fostered thereby constitutes a part of the social milieu in which American psychiatrists choose their careers and do their work. There are occasions when one is inclined to deplore the exaggerated expecta-

tions sometimes generated by psychiatric "public education." For example, some American mothers have been thrown into great anxiety, which has driven them to seek frantically for fixed rules as to the right method for bringing up children.

Yet it seems probable, on the whole, that the American public is being led to develop more naturalistic ideas about mental illness in place of age-old attitudes of horror and superstitious aversion. The net result in the long run should therefore be constructive, although temporarily we may suffer from prematurely crystallized and prematurely popularized hypotheses.

At present, American psychiatrists appear to be in a mood of dedicated optimism and therapeutic fervor, contrasting markedly with the pessimism or therapeutic nihilism of the preceding generation. Even in the presentation of the statistical size of the psychiatric problems, Americans manifest currently, by implication if not outspokenly, an underlying optimistic obligation, as if to say, "See what a problem we have! Something must be done about it, and something will be done about it!"

In our therapeutic eagerness we may, in the eyes of our foreign friends, manifest a somewhat excessive enthusiasm regarding the measures we happen at the moment to be using. Our psychiatric journals reflect these waves of enthusiasm, and even more, the daily press, but these media do not in true measure reflect the more sober conservatism of the larger number of psychiatric practitioners; hence those who know us only through our journals or newspapers are likely to get a somewhat exaggerated idea of this over-enthusiasm.

The present rather characteristic American mood of therapeutic eagerness, although welcomed for its constructive force, has given concern to some of us in close touch with the young men and women entering upon careers in psychiatry. We had a strong surge of enthusiasm in the forties for psychodynamic formulations and psychoanalytic therapy;

¹ Read at the Symposium, "Perspectives on International Psychiatry," at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore, Md.

now we are in the midst—perhaps only at the beginning—of a wave of enthusiasm for a *pharmacodynamic* approach. The general atmosphere of obligation to cure seems at times to deaden a bit the eagerness and the industry available for the hard tasks of gaining more fundamental understanding. Pre-occupation with therapy seems at times to have somewhat the quality of an obsessional neurosis. The appeal of therapeutic practice—an appeal which is emotional as well as financial—appears to outshine, for some of our ablest young psychiatrists, the appeal of the investigative work. Fortunately, this tendency has not been altogether sweeping.

One manifestation of the increasing public interest and optimism regarding psychiatry in America has been the increase in funds made available for psychiatric research both by private philanthropy and from Governmental sources. A considerable proportion of these millions of dollars is being put into studies which we now like to call "behavior sciences." If the intensive cultivation of this field by the project method *can* be counted on to produce fruitful results, the next scientific generation should understand behavior better. It could be, however, that we will merely get newer and more elaborate versions of behaviorism. The problem of wisely expending such increasing funds has been a matter of much concern, with a tendency to rely heavily upon advisory committees and boards to select fruitful projects. There are grave dangers of waste and ineffectiveness in expending research support on committee-selected projects of relatively restricted operation and duration. In this way, support is more readily obtainable for the hypothesis-testing function of science than for creative work. Experimental design gets priority in committee deliberations over the capacity to generate ideas and to stimulate the investigative work of students. When I spoke before this Association 6 years ago, upon the role of the university in medical education and progress, I commented rather harshly upon the disadvantages of the project type of supporting research. It seemed that the American public was being led to expect that the fruits of science could be regularly obtainable without giving basic support to the educational and scholarly enterprises which nourish

the roots of the tree, through free inquiry and unrestricted curiosity. Others have also spoken, more effectively, to the same purpose; and there is coming about a slow and gradual, but perceptible, liberalization of the terms and conditions of research grants. The American people have always given generous support when their interest was aroused, but we as a people have been somewhat impatient about basic research, and are only now gaining an appreciation of the slow and undramatic processes involved in basic scientific progress. We have tended to think of research as a job to be done rather than as a thought to be pursued, wherever it might lead, and so we run, by habit, towards surveys or projects.

This Association is at present engaged, with other related professional groups, in a three-year survey by a selected task force, of the problems of mental health in America. One result of that survey will undoubtedly be a comprehensive report, depicting truly the present actual situation in American psychiatry in contrast to the impressionistic sketch I now present. This survey will assuredly provide a graphic picture of the psychiatric tasks, and a critical review of the institutionalized agencies currently employed to perform those tasks. I hope that it will also attempt to depict the germinal ideas, so far as they can be ascertained, which as yet may have no direct application in the mental health field, but which in fundamental ways may deepen our basic understanding of the psychiatric problems. The survey will not of course be altogether successful in pinpointing these basic concepts. Some of them have not yet been conceived, and some conceptions that will in time be fruitful may look at present pretty insignificant. But it is one of the great needs in America to devote a larger share of its available support to the unrestricted research which is potentially productive of basic ideas, in situations most favorable to creative thought and to the stimulation of oncoming students, *i.e.*, primarily in the universities. There is evidence, as I say, of a movement for greater support in this way to nourish the roots of creative investigation; and the survey by the Joint Commission will, I hope, emphasize the sound strategy of that mode of cultivating knowledge.

The social sciences are receiving currently considerable support in the name of psychiatric research, and this tendency is in accord with the prevalent emphasis in American psychiatry upon the social implications of mental and emotional illness—an emphasis upon social implications which has for half a century persistently characterized American psychiatric thinking, beginning early in this century in Dr. Adolf Meyer's interests, (1) in the development of social habits, (2) in the influence of school life on personality development and (3) in the individual person's use of the consensus for the maintenance of a healthy outlook on life.

Characteristic American interest in the basic social implications of psychiatric illness also found expression in Harry Stack Sullivan's interpersonal formulations, in more recent transactional formulations as exemplified by Grinker's group of investigators, and in the reformulations of psychiatric and psychodynamic problems in terms of social roles, as expounded by Norman Cameron, and more recently by John Spiegel. Erik Erickson's recent studies of the adolescent's struggles over ego-identity may be grouped also with these socially-oriented psychodynamic studies. The basic ideas of Sigmund Freud have strongly influenced these developments.

It may be that the preoccupation of American psychiatrists with the social environment is a reflection of our cultural history as a melting pot for people from widely differing cultural backgrounds, and the extensive cultural changes which have accompanied internal migration, incident to industrialization and urbanization.

Moreno's sociometric methods of study and his psychodramatic methods of therapy have exerted a stimulating influence on the study and utilization of social forces in psychiatric work.

A growing tendency toward collaboration between psychiatrists and religious leaders has been a feature of some of the experiments in social psychiatry, such as those of Eric Lindeman in New England. Our president has just taken the lead toward further collaboration.

The social worker has long been a close collaborator with the psychiatrist in America.

Without displacing the social worker, the sociologist and the cultural anthropologists have more recently become working partners also, in the direct study of the social and cultural implications of mental health problems. The studies by Redlich and his collaborators at Yale provide a good illustration of the "multidisciplinary method," so-called, for the study of the social environment. Alex Leighton's project in Nova Scotia and Tom Rennie's study of an urban population in New York City are American examples of social psychiatry. Added stimulation to this social trend of psychiatric thought has come from the classical study by Stanton and Schwartz of the mental hospital as a dynamic social system.

In relation to this socio-dynamic trend, it is significant to note that in many discussions of drug therapy—e.g. chlorpromazine—special emphasis is placed upon the improvement in the social milieu of the mental hospital ward, and upon the challenge thus presented to the better use of personnel and of the social milieu for basic therapeutic purposes.

In a less mature period of American psychiatry we witnessed much dispute and rivalry between those who advocated an environmental approach and those who advocated a pharmacological approach to the management of behavior disturbances. Now we see, in a practical way, how these different approaches should not be rivals, but supplements to each other.

Here is a good point at which to raise the question, how does American psychiatry deal now with the old question of heredity and environment? In sheer bulk of psychiatric literature, the social environment receives from American psychiatrists the much greater emphasis.

In contrast, it is often remarked that the psychiatrists of the European continent have emphasized biological and hereditary factors in mental illness. The twin-studies of schizophrenic patients by Kallmann in New York have brought forcefully to the attention of American psychiatrists the probable importance of constitutional factors in the determination of schizophrenic types of reaction. Kallmann's accumulation of data has also served to clarify the point that genetic in-

fluence does not mean inevitability—that identical twins do not invariably come to the same end, thus posing the question how to make the most constructive possible use of differential life experiences and differing ways of using identical genetic endowments of combinations of favorable and unfavorable factors. At present, this question provides a topic for discussion, but we have not integrated such considerations into practical programs for action, or even for experimental investigation. The possibilities of deterioration of human material through more effective care of the constitutionally deficient, is occasionally commented upon, but there does not appear to be any concerted program toward genetic control, such as we had in the first two decades of the 20th century.

The biological aspects of psychiatry are probably due for an extensive reappraisal in the light of much recent neurophysiological investigation in America. The work of Magoun on the reticular substance has particularly aroused much interest because of its probable pertinence to clinical phenomena of anxiety and motivation and to the effects of so-called tranquilizing drugs.

The wave of interest in psychotherapy is strongly maintained and constitutes one of the marked characteristics of American psychiatry. This interest is not confined to the practical applications, but is manifested also in a fair number of studies designed to throw light on the nature of the psychotherapeutic processes. The publications by Powdermaker and Frank and their associates on their studies of group therapy provide examples of the manner in which it is possible to take advantage, for investigative purposes, of the relatively more public and exposed operations of the group, as compared to the privacy of individual psychotherapy. Special psychological interest has been focussed upon the learning process, because of its probable significance both in the therapy and in the pathogenesis of emotional illness.

One of the most distinctive recent features of American psychiatry, as observed by foreign visitors, is the large role played by psychiatrists in medical education—particularly in the "basic science" aspects. The prototype for such teaching was Adolf Meyer's course in psychobiology, in which students

were oriented by a holistic approach to human nature in illness and in health, with special attention to the existence of different levels of integration and with special emphasis upon the symbolic level. Great diversity now exists in the different medical schools in this aspect of teaching, but in general it may be said that the emphasis is upon psychodynamic, humanistic and sociological considerations in medical problems. "The patient as a person," is the key phrase. Collaboration with internal medicine, pediatrics and social service in teaching medical students constitutes a significant part of this expanded program of psychiatric instruction.

It is probably significant to say that the chief aim of such educational efforts is attitudinal rather than informational, even though that distinction may be somewhat artificial. In one experiment there was an attempt at a kind of massive group psychotherapy upon the medical students, but that plan has not been approved or followed by others.

In some measure, the efforts put into these early courses for medical students represent the desire to cultivate a humanistic approach to medical problems. Some foreign observers have seemed puzzled as to why in American medical education this aspect should be a responsibility of psychiatry. Admirers of psychiatry are likely to explain this by saying that psychiatrists are the medical specialists who have felt most keenly and have responded most adequately to the necessity of comprehending and synthesizing the fractional views of patients in a comprehensive understanding of the patient as a person. It is also stated that psychiatry got ahead of other branches of medicine in its appreciation of personality and temperament and in the practical development of methods of studying human personality.

I have expressed these points in cautious language, because I cannot quite go along with those who would claim all the credit for psychiatrists. For many years I have been deeply impressed by the human qualities shown by internists, surgeons and other specialists in their positive concern for patients' welfare and the respect and consideration they have shown to patients. One man

festation of these attitudes, which is fairly typical of American medical practice, has been the *regular* thoughtful discussions by doctors with their patients, designed to help the patient understand his medical problem and exercise wisely his freedom of choice and his possibilities for constructive partnership in medical or surgical or other measures aimed at his best health and best functioning. If we make the point that psychotherapy is a special elaboration and intensification of this procedure of talking things over, and its special application to problems of emotional difficulty and social maladjustment, we perceive a considerable unity of psychiatry with general medicine, as the role of doctor and patient have developed in the American culture. One of the most brilliant and most effective discussions of the patient as a person has been written by an eminent American internist, Francis Peabody. Psychiatrists, collaborating with others in the type of teaching which I have been discussing, have gained as well as given.

It is now a characteristic feature of Ameri-

can medical education that the psychiatric teacher starts quite early with the students and does provide considerable instruction in the basic concepts for the intelligent understanding of human behavior and human reactions of patients.

In bringing to a close this brief impressionistic sketch of American psychiatry, I should make it clear again that I have chosen to stress what have seemed to me the most distinctive features. This attempt at broad characterization should be supplemented by a look at this program of our annual meeting, and a quick mention of the numerous regional conferences, the mental health institutes devoted to the problems of the mental hospitals, and the organizational structures developed by this Association, such as the Hospital Service, the Central Inspection Board and the Architectural study project. In these ways we manifest our numerous common interests with the psychiatrists in all countries, as well as our characteristic American tendency to get organized for cooperative enterprises.

GROWTH AND AGING

EDWARD L. BORTZ, M.D.^{1, 2}

THE GROWING PROBLEM

For a good many years I have been interested in problems of aging, the changes in man which appear with the passage of time.

Medicine must be concerned with the deep dissatisfactions of our aging citizens; if for no other reason it is because of the spectacular increase in numbers. This is a huge problem for society to solve. It is becoming evident that the health, medical and welfare problems of our senior citizens is the number one challenge to our nation today. There is a vast amount of waste of human resources represented in the elder population, many of whom are being retired and thereby rendered inactive just at the time when their great needs are continued opportunity for employment and participation in the busy world.

The duration of life today is just about double that of a century ago. In 1930 there were 6½ million of 65-year-olds and in 1956 the number was approaching 15 million.

These elder citizens are an entirely different kind in body and vitality than the elders of an earlier day. Not only are they living longer: they are capable of retaining buoyancy and usefulness far into the higher years. Furthermore, there is high promise on the horizon that, in the next 10 years, a great deal of extremely important information concerning the most common wear and tear disorders of aging bodies will be formulated. Then, when this happens, there will be another substantial extension of the human life span.

I am unhappy because our medical leaders, especially those responsible for training doctors have, until now, shown little inclination to come to grips with this expanding issue.

Aging is a human dimension which can be measured chronologically. But more impor-

tant, biological aging is to be measured in terms of organic tissue changes, performance, repair and recession. There is rhythm in this living world, and beauty and design. Certain broad patterns are beginning to crystallize. Highly refined scientific techniques are now being developed. Man's battle with time is a problem of energy dispersion. In many ways it is now becoming possible to control the rate of human energy dispersion.

Hooton, the caustic Harvard anthropologist, had a point when he observed that medical science, instead of starting at the autopsy table and working backward, logically should begin its studies with the healthy fetus and child, then work forward. This makes sense. It seems to me we are still proceeding backward. It is a most inefficient, illogical dissipation of national resources to be training more doctors, more nurses and building more badly planned hospitals for more and more sick, unhappy, fearful and inefficient aging human beings.

We are entirely missing the great opportunity to encourage aggressively the development and flowering of human potentials. There should be fewer sick people. Our present national policy is to encourage people to get sick. Apparently it excites our compassion. We encourage them to expect security. We retire many, just when they are most productive. There is desperate need for a complete and radical about-face in our entire national philosophy regarding our aging population.

Geriatrics, a term I dislike, has slow going. Doctors shun the aged. Our medical scientists today are much fascinated by the love-life of bacteria and the excursions of electrolytes but they walk by our aging brother and look the other direction. It is true that in practically every community there is a huge need for facilities to house and feed and protect those far spent in their life journey. Our greater opportunity, and here we must sharpen our tools, is in finding ways and means to improve the physical and mental fitness of our 40-, 50-, and 60-year-olds as

² Address: 2021 West Girard Ave., Philadelphia 30, Pa.

they age; to study their performance, their opportunities and desires and particularly to keep them busy and strong; in other words to promote energetically their health potentials. There is a ferment over the land, as revealed by the creation of councils and committees on aging and mental health, which is encouraging evidence that the public is reaching out for help in its search for emotional balance and stability.

Congress has voted an initial 16 million dollars to support studies of aging alone and much more is available for mental health. Scientific psychiatry as it probes the psychodynamics of behavior is looming as the bright hope of a troubled world. There is also need for re-examination of social pathology with the newer techniques. We are sailing uncharted seas. It is a thrilling and exciting experience. The majority of medical problems have a dynamic psychic component. The time has come when general medicine and psychiatry now have a common meeting ground in the growing recognition of the mind as the measure of the man. We like to think of ourselves as rational beings. It was Benjamin Franklin, I think, who sagely observed that "the reasonable man is he who finds a reason for everything he wants to do."

Reason is usually influenced by feelings deeper than rational processes extend. Subconscious motivations exert their pressure. A healthy mind, socially focused, is the prime objective of medical practice. With passing time, from youth to age there should be a ripening, maturing sense of living.

Child guidance is an accepted procedure today. It was the psychiatrist early in the twentieth century who recommended freedom of expression for the young mind. In no way was the child to be denied the free play of all his random impulses. So we had the decades of the youth movement. The parent was subservient to the adolescent. Those in the later years were passive. And with the passage of time they became dependent on the adult children, a state of reverse responsibility. With this over-emphasis on youth there has been a cultural exclusion of the elderly. The older they grow the more isolated they tend to be. They become obso-

lescent just when they should be enjoying a greater recognition and prestige because of their maturity and social usefulness. What I want to emphasize is, that current practices and community customs depreciate the old. They in turn react by withdrawal from active pursuits. And the stage is set for the neuroses and depressions so common in the aged. With recession comes decay. Countless case histories attest the validity of this statement.

I believe an age movement is on the way which will supplement the youth movement.

With this new awareness it is possible to identify the precursors of disease. If we can estimate the physiological and psychological status of our older patients, and if we can increase their reserves there will be fewer premature breakdowns. We should, as a profession, endeavor to improve the stamina and fitness and thereby increase the capacity for performance and enjoyment of mature citizens. Merely curing the various ailments is a negative hit or miss, stop-gap practice which is woefully inefficient, expensive and unrealistic. Such a medical service falls far short in raising levels of community health. In brief, we as a profession, should become health-oriented rather than disease oriented. Concerning the potentials of our older citizens let us take from the altars of the past the fire and not the ashes.

BIOLOGICAL RHYTHMS

Studies of aging encompass the growth and development of the individual throughout the life span. Various tissues within the body have different time cycles for maturation, apparently determined by their particular usefulness to the body economy. Cowdry has shown that within a single body aging proceeds at different speeds. It is well known that practically all the tissues in the body are replaced by new material, molded in the same shape.

Gerontology is concerned with problems of growth, development and maturation, just as much as with atrophy, degeneration and decline. I see in the fascinating, continually changing processes constantly going on within the body, a balance and beauty and harmony. Human development, maturation

and aging follow a definite biological sequence. The unfolding of the life pattern, year after year, from childhood to the summit of maturity is a thing of beauty.

Nature has expressed herself in rhythmic patterns and balances. There are the recurring rhythms of the circulation, the digestive tract, of action and repose. In the mind world each of us has experienced alternating moods of elation and let-down. Warthin has emphasized the rhythm present in all aspects of human growth and development.

There appears to be a definite timetable for each tissue and organ not basically chronological, but a reflection of inherent vitality or the lack under adverse conditions. The life span of certain transient tissues, as the placenta, the ovaries and certain other glands is strictly limited. The life span of any particular body tissue differs from that of the body as a whole. There are certain tissues as described by Cowdry which are veritable fountains of youth. The cells of the bone marrow and certain cells within the eye might be classed as potentially immortal.

Few individuals attain the optimum span because of preventable human deterioration. It has been pointed out by Dr. Charles L. Dunham, Director of the Atomic Energy Commission Division of Biology and Medicine, that the early detection of tissue breakdown can now be made by radioactive isotopes pinpointing defects in the early stages. He thinks these deteriorations can be protected. For the first time scientists have an important new tool for studying growth, development and recession.

The radioactive isotope as a labelled tracer for studying the minutiae of intermediary metabolism, hormone and enzyme actions and the processes of cell regeneration, particularly of nerve cells, is a discovery of importance equal to that of the discovery of the microscope. This new procedure is already paying generous dividends. We now have at our command considerably more information of the requirements for healthy aging. It all adds up to a healthy body for many extra years. Enlarging biological patterns permits more opportunity for emotional, intellectual and spiritual growth.

A. J. Carlson commented on this when he

pointed out that, at last we are approaching an era in which man lives long enough to have time to think. In thinking he grows, and in growing, lives. In other words, he can grow as he ages.

The major dominant in human development is concerned with emotional maturity. In an article entitled "The Third Side of Growth," presented some years ago by Earl Bond, certain ideas were offered which are of especial significance today. Briefly, he called attention to physical and intellectual growth as following a fairly well accepted sequence of development. To these he added a third phase, emotional growth and maturation as the dominant force within an individual. Bond outlined in that paper the goals which modern psychiatry is hoping to achieve in the field of mental health. He stressed self-reliance, productivity, flexibility, tolerance, moderation in mood, the ability to look ahead, the ability to live on the growing edge, religious orientation, and serenity. With years added to life there is more time available for growth. This is essential in order that a final vegetative existence be avoided. Maturity then, is a dynamic phenomenon, a continuation of growth as long as health and vitality exist. Present thought indicates that with health and vitality being preserved into the higher years more time for maturation becomes available.

In one of Bernard Shaw's essays, "Back to Methuselah," he makes the point that longer life is a necessity if mankind is to survive the present civilization. Much of the social illness today is the result of immature minds. Psychological maturity is defined as the master concept of our time in a popular best seller, *The Mature Mind*, by Overstreet. The maturity concept is central to the whole business of modern life. It offers a solution for the confusions and despairs of the present day. The American Psychological Association has carried on important researches in this field. Psychology is now weighing methods of research to define the criteria of maturity.

The growth timetable may be divided into certain specific categories each of which under favorable conditions progresses through a developmental period to full maturity.

Physical maturity is defined anatomically as that period when the epiphysis and diaphysis of the long bones of the body fuse permanently. Physical growth is then completed. In lower animals there is a fairly close relationship between the period required to attain full body growth and the life span of the animal. For example, in the dog it takes 2 years for the shaft of the long bones to unite and the average span of life is 12 years, for the cat $1\frac{1}{2}$ years and the average span of life is 9 to 12 years. A horse requires $2\frac{1}{2}$ to 3 years for physical maturity and lives approximately six times three or 18 years.

If the human body attains physical maturity at approximately 25, the average span of human existence should approximate 125 to 150 years. Physical maturity is a relatively simple phenomenon and all that is required today is a well-balanced nutritional program and unimpeded opportunity for normal growth.

Intellectual growth is systematized by our school systems. Progression from one grade to another in regular sequence may be followed through college into areas of research. Intellectual maturity is attained by a fully prescribed educational program. A high degree of literacy is a mark of an advanced culture.

For emotional growth there is not the well systematized progression which the schools furnish for intellectual development. This third phase of growth should proceed to emotional maturity described as the master concept of our time. Finally, spiritual maturation is characterized by understanding, tolerance, wisdom, and religious orientation.

The growth timetable for these components of human existence are not parallel. While there is overlapping, physical maturity would seem to be followed by intellectual, emotional, and finally spiritual fulfillment. Under optimum conditions, the growth of these interdependent components should enhance the maturation of the individual.

RECHARGE MECHANISMS

To offset the diffusion of energy as time passes, the human body has an amazing ca-

capacity to renew itself. As Kubie points out, the animal body is the only machine which has a built-in replacement system, its own self-replenishing devices. In its rhythmic, changing dynamics each cell, each molecule is renewing itself, and continues even under mounting adverse conditions. Resistance to deterioration is revealed in the recuperation processes of all body cells. Experimentally seven-eighths of the liver can be removed from an experimental animal and the organ will recreate itself. An animal can be rendered diabetic by overloading with glucose or by alloxan. When the noxious agent is removed the cells return to normal, provided the insult has not lasted too long.

By attention to diet the life span of experimental animals can be doubled. Their vitality and sex potency can be preserved to an equivalent of an 85-year old woman. Homeostatic mechanisms, freed of overloading and exhaustion can maintain balanced function far beyond the average time.

What interferes with this self-perpetuating mechanism within each cell? What are the barriers to healthy aging? Suppose science solves the riddle of arteriosclerosis, cancer and nervous exhaustion? There is already exciting evidence that we are on the verge of the control of these diseases.

Numerous observers have estimated that man uses only a small portion of his physical and mental powers. If we control the diseases and deteriorations of human tissues, a fantastic future awaits us. As Kubie writes, we are at the frontier of an exciting new existence.

It is not the muscle man society needs today. If medicine is concerned with more than man's physical ailments, then the mental disorders, hopes, fears and yearnings which reveal the values each individual cherishes—these are the concerns not exclusively of psychiatry, but of the entire profession.

The new fields of psychodynamics and analysis have brought out into the open hidden purposes behind behavior. The driving forces of the individual are now coming within the sphere of objective study. These techniques are capable of revealing the barriers to man's emotional maturation.

THE SEARCH FOR DESIGN

The changing fabric of society as it reflects the impact of more and more older people is creating many vexing problems which defy traditional methods of solution. It is a curious paradox which science has created. The life span is certainly, if slowly, increasing. Citizens in the future may ordinarily live 100 years. We already have the know-how to eliminate many nuisance disorders by promoting fitness. In fact, we might well inquire at this time, what are the basic needs of each of us as we grow into the later years? I believe the three most necessary essentials are first, an adequate but limited food supply; second, the control of exhaustion; and third, a high specific motivation. These promise fitness for survival, and an enjoyable and sociable experience. Around each need there should be a generous margin of reserve. These aspects of biological experience, growth, maturation and aging are now capable of reasonably accurate measurements.

In his address as the retiring president of the American Association for the Advancement of Science in 1956, Beadle stated that man's evolutionary future, biologically and culturally is unlimited. But, far more important, it lies within his power to determine its course. Man is potentially capable of self direction. He could, to a much greater extent than he now does, consciously select his cultural objectives. He could, although he

has not yet recognized it, control his own biological future. He is now in a position to transcend the limitations that for so long have set his course. Beadle shows that to obtain biological and cultural freedom, knowledge, collective wisdom and courage, plus faith are required. In his uniqueness man is capable of attaining heights far greater than his most magnificent cultural achievements of the past.

In our increasing understanding of nuclear energy it is now known that there are hidden forces of undreamed of power within each human body and mind. In fact, atomic theory describes the atom as vibration. It can be interpreted as music, atomic energy can be equated in musical harmonies. In this way all matter is related. It in reality has religious significance. For, if energy is indestructible, then human beings continue to exist albeit in different phases.

Shelley had this in mind when, in his poem "The Cloud," the rain drop speaks:

"I am a daughter of the earth and a nursling of the sky;
I pass through the pores of ocean and shores,
I change, but I cannot die."

Above the daily routine world we are participants in a great social experience. In the presence of the awesome power now revealed to us in this atomic age, may we attain the wisdom to utilize the newly available energy so that our fellow man may walk on higher ground.

PERCEPTION AND INTERPERSONAL RELATIONS¹

HADLEY CANTRIL²

It is with a very profound feeling of humility that I, as a psychologist, offer any comments for the consideration of psychiatrists on the subject of perception and interpersonal relations. For the more one studies perception, the more one sees that what we label "perception" is essentially a process which man utilizes to make his purposive behavior more effective and satisfying, and that this behavior always stems from and is rooted in a personal behavioral center. Thus perception involves numerous aspects of behavior which we rather artificially and necessarily differentiate in order to get a toe-hold for understanding, but which, in the on-going process of living, orchestrate together in a most interdependent way.

This means, then, that the nature of perception can only be understood if somehow we manage to start off with what some of us call a "first person point of view" as contrasted to the "third person point of view" represented by the traditional psychological investigator. And so my very genuine feeling of humility in accepting an invitation of psychiatrists derives from the fact that the psychiatrist, perhaps more than any other specialist concerned with the study of human beings, is primarily concerned with the first-person point of view, is skilled in the art of uncovering what this may be for his patient, and knows from his own experience the wide gap that exists between this first-person experience and the abstractions we have created as scientists in order to analyze, conceptualize, and communicate. A very nice expression of this last state of affairs was, incidentally, recently made by Aldous Huxley in his book *The Genius and the Goddess*:

"What a gulf between impression and expression! That's our ironic fate—to have Shakespearian feelings and (unless by billion-to-one chance we happen to be Shakespeare) to talk about them like automobile salesmen or teen-agers or college professors.

We practice alchemy in reverse—touch gold and it turns to lead; touch the pure lyrics of experience, and they turn into the verbal equivalents of tripe and hogwash."

BACKGROUND

Most of you are probably familiar to some extent with a point of view that has developed rather recently in psychology and has been dubbed "transactional psychology." While I do not want to spend time here repeating what has been published in a variety of sources, I might at least very briefly note some of the major emphases of transactional psychology before discussing certain aspects and some experimental results which may be of particular interest to psychiatrists (1, 2, 3, 4).

Here, then, are some of the emphases of transactional psychology which may give us a take-off for discussion:

Our perception depends in large part on the assumptions we bring to any particular occasion. It is, as Dewey and Bentley long ago pointed out, not a "reaction to" stimuli in the environment but may be more accurately described as a "transaction with" an environment.

This implies that the meanings and significances we assign to things, to symbols, to people, and to events are the meanings and significances we have built up through our past experience, and are not inherent or intrinsic in the "stimulus" itself.

Since our experience is concerned with purposive behavior, our perceptions are learned in terms of our purposes and in terms of what is important and useful to us.

Since the situations we are in seldom repeat themselves exactly and since change seems to be the rule of nature and of life, our perception is largely a matter of weighing probabilities, of guessing, of making hunches concerning the probable significance or meaning of "what is out there" and of what our reaction should be toward it, in order to protect or preserve ourselves and our satisfactions, or to enhance our satisfac-

¹ Read at the A.P.A. Regional Meeting in Montreal, Nov. 8-11, 1956.

² Address: Institute for International Social Research, 240 Nassau Street, Princeton, New Jersey.

tions. This process of weighing the innumerable cues involved in nearly any perception is, of course, a process that we are generally not aware of.

CREATING CONSTANCIES

Since things in the world outside us—the physical world and more especially the social world—are by no means static, are not entirely determined and predictable, experience for most of us often carries at least some mild overtone of “concern” which we can label “curiosity,” “doubt” or “anxiety” depending on the circumstances involved.

One of my favorite illustrations of this point is an incident described by Carl Sandburg in his autobiography, *Always the Young Strangers*.

“I have always enjoyed riding up front in a smoking car, in a seat back of the ‘deadheads,’ the railroaders going back to the home base. Their talk about each other runs free. . . . Once I saw a young fireman in overalls take a seat and slouch down easy and comfortable. After a while a brakeman in blue uniform came along and planted himself alongside the fireman. They didn’t say anything. The train ran along. The two of them didn’t even look at each other. Then the brakeman, looking straight ahead, was saying, ‘Well, what do you know today?’ and kept looking straight ahead till suddenly he turned and stared the fireman in the face, adding, ‘For sure.’ I thought it was a keen and intelligent question. ‘What do you know today—for sure?’ I remember the answer. It came slow and honest. The fireman made it plain what he knew that day for sure: ‘Not a damn thing’ . . .”

Thus we seldom can count on complete 100% surety in terms of a perfect correspondence between our assumptions concerning the exact experience we may have if we do a certain thing and the experience we actually do have as the consequence of the action we undertake.

In an attempt to try to minimize our potential lack of surety concerning any single occasion and thereby maximize our sense of surety concerning the effectiveness of our action in achieving our intent, we build up “constancies” and begin to count on them. While a great deal of experimental work has been done on “constancies” in the psychological laboratory, we still have much more to learn. And above all, we have a great deal to learn about constancy as we

extend this concept into the field of our interpersonal relations.

Parenthetically, one of the most important things we have to learn is that the “constancy” we create and that we describe usually by means of some word, symbol, or abstract concept is man’s creation, the validity of which can only be tested and the meaning of which can only be experienced in terms of some behavior which has consequences to us and signals to us what the concept refers to.

We create these constancies by attributing certain *consistent* and *repeatable* characteristics to what they refer to, so that we can guess with a fair degree of accuracy what the significances and meanings are of the various sensory cues that impinge upon us. We do this so that we will not have to make fresh guesses at every turn.

These significances we build up about objects, people, symbols, and events, or about ideas all orchestrate together to give us what we might call our own unique “*reality world*.” This “reality world” as we experience it includes, of course, our own fears and hopes, frustrations and aspirations, our own anxiety and our own faith. For these psychological characteristics of life—as the psychiatrist knows better than anyone else—are just as real for us in determining our behavior as are chairs, stones or mountains or automobiles. It seems to me that anything that takes on significance for us in terms of our own personal behavioral center is “real” in the psychological sense.

ASSIGNING SIGNIFICANCES

Let me illustrate with reference to a few recent experiments the way in which the significance we attach to others “out there” seems to be affected by what we bring to the situation. Incidentally but important: I do want to underscore that the experiments mentioned here are only exploratory; are only, I believe, opening up interesting vistas ahead. I am in no sense attempting to indicate what their full theoretical implications may be. But I mention them to show how experiments designed to get at the first person point of view may suggest to the experienced psychiatrist ways of using experimen-

procedures in his diagnosis and possibly in therapy. And I also mention them because of my deep conviction that psychology can be both humanistic and methodologically rigorous.

A whole series of most promising experiments now seems possible with the use of a modern adaptation of an old-fashioned piece of psychological equipment, the stereoscope. Dr. Edward Engel who devised the apparatus has already published a description of it and reported some of his first findings(5). As you know, the stereoscope in a psychological laboratory has been used to study binocular rivalry and fusion but the material viewed almost always consisted of dots and lines or geometrical patterns. Engel was curious to see what would happen if meaningful figures were used instead of the traditional material.

The results are really most exciting. In Engel's experiments he prepares what he calls "stereograms" consisting of photographs 2×2 inches, one of which is seen with the left eye, the other with the right. The photographs he used first were those of members of the Princeton football team just as they appeared in the football program. Although there were slight differences in the size and position of the heads and in the characteristics of light and shadow, still there was sufficient superimposition to get binocular fusion. And what happens? A person looks into the stereoscope and sees one face. He describes this face. And it almost invariably turns out that he is describing neither the face of the man seen with the left eye nor the face of the man seen with the right eye. He is describing a new and different face, a face that he has created out of the features of the two he is looking at. Generally the face seen in this particular case is made up of the dominant features of the two individuals. And generally the face created by the observer in this situation is more attractive and appealing than either of those seen separately. When the observer is shown the trick of the experiment by asking him to close first one eye and then the other and to compare the face he originally saw with the other two, he himself characterizes the face he created as more handsome, more pleasant, a fellow he'd like better, etc.

I hasten to add, however, that we should by no means jump to the conclusion that an individual picks out the "best" or "most attractive" features of figures presented to him in a situation of binocular fusion. For example, Professor Gordon Allport recently took one of Engel's stereoscopes with him to South Africa and initiated some experimental work there, using photographs of members of the different racial groups which make up that complex community.

While the experiments in South Africa have only just begun and no conclusion should be drawn, it is significant to note that in recent letters communicating the early results, Allport reported that when the stereograms consist of a European paired with an Indian, a colored person compared with an Indian, etc. the Zulus see an overwhelming preponderance of Indians. For the Zulu is most strongly prejudiced against the Indian who represents a real threat to him. Allport also reports that when Europeans in South Africa view the stereogram they tend to see more colored faces than white. It would seem, then, that a person sees what is "significant," with significance defined in terms of his relationship to what he is looking at.

One pair of slides we use in demonstrating this piece of equipment consists of two stereograms, each a photograph of a statue in the Louvre. One of the statues is that of a Madonna with Child, the other a lovely young female nude. While I am unable so far to predict what any given individual will "see," no doubt such a prediction might be made after some good psychiatric interviewing. But let me describe what happened in a typical viewing of these stereograms. The viewers happened to be two distinguished psychologists who were visiting me one morning, one from Harvard, the other from Yale. The first looked into the stereoscope and reported that he saw a Madonna with Child. A few seconds later he exclaimed, "But my God, she is undressing." What had happened so far was that somehow she had lost the baby she was holding and her robe had slipped down from her shoulders and stopped just above the breast line. Then in a few more seconds she lost her robe completely and became the young nude. For this particular professor, the nude never did get

dressed again. Then my second friend took his turn. For a few seconds he could see nothing but the nude and then he exclaimed, "But now a robe is wrapping itself around her." And very soon he ended up with the Madonna with Child and as far as I know still remains with that vision. Some people will never see the nude; others will never see the Madonna if they keep the intensity of light the same on both stereograms.

In the situation described above, we do not have conditions for genuine fusion, but rather a condition which introduces conflict and choice in the possible meaning of the content represented. In order to learn whether or not there might be differences in choice that would be culturally determined, a cross cultural comparison was made by Dr. James Bagby (6). He constructed pairs of stereograms that would create binocular rivalry: in one stereogram of each pair he had a picture of some individual, object or symbol that would be of particular interest to Mexicans; in the other stereogram he had a picture that would be of particular significance to Americans. For example, one pair of slides consisted of a picture of a bull fighter matched with a stereogram picturing a baseball player. When these pairs were shown to a sample of Mexican school teachers, an overwhelming proportion of them "saw" the Mexican symbol; when the same slides were presented to a group of American school teachers, the overwhelming proportion "saw" the American symbol.

Incidentally, the Engel stereoscope is so constructed that one can get some idea of the relative "strength" of each of the stereograms by adjusting the intensity of the lighting on each. Hence, if the lighting is equivalent on two stereograms in a rivalry situation, one can reduce the amount of lighting on the one that originally predominates, increase the amount of light on the one that was not "seen" and find the point where the first one disappears and the second one "comes in."

A modification of the stereoscope has just been completed by Mr. Adlerstein in the Princeton laboratory. Our thought was that it might be extremely useful both in the clinical and social areas, if instead of having to use photographs of objects or people, a person could view the real thing—that is, the

faces of real, live individuals or pairs of actual objects. So by means of prisms and mirrors, this device was constructed and I have only very recently had the opportunity of experiencing the resulting phenomena. I must say it is strange and wonderful. For example, when I viewed Mr. Adlerstein and Mrs. Pauline Smith, Curator of our Demonstration Center, I seemed to be looking at a very effeminate Mr. Adlerstein who was wearing Mrs. Smith's glasses. Though weird, he was extremely "real." At one point while I was observing them Mrs. Smith began to talk yet it was Adlerstein's lips that were moving! Tingling with excitement and with a certain amount of anxiety, I drove home and asked my wife and daughter to come down to the laboratory so that I could take a look at them. I was, of course, fearful that I might see only one or the other. But fortunately, again I got an amazing fusion—a quite real and lovely head composed of a blending of my daughter's hair and chin and my wife's eyes and mouth—an harmonious composition that would do justice to any artist and which I created almost instantaneously and without any awareness of what was going on. These pieces of apparatus seem to me to have enormous potential usefulness for studying the way in which we create the world around us. I am hoping, for example, that before long someone in a position to do so may use this sort of equipment in a study of disturbed children. The child—having two eyes and two parents—might in some situations and in a very few seconds reveal a good bit about his inner life and his interpersonal family relations.

An interesting series of experiments on perception and interpersonal relations began systematically a few years ago after an observation I made one Sunday morning in our laboratory. An old friend of mine, who was a distinguished lawyer in New York and has since died, called me at home to say that he and his wife had been in town for the weekend and would I be willing to show them some of the Ames' demonstrations about which he had heard. It is important for this story to emphasize the fact that the gentleman in question was really a most unusual man in terms of his ability, charm,

accomplishments, and his devotion to his family and friends.

Many of you are familiar, I am sure, with the "distorted room" designed by Adelbert Ames, Jr. which produces the same image on the retina as a regular square room if it is viewed monocularly from a certain point. Since the room is seen as square, persons or objects within the room or people looking through the windows become distorted. I had shown this room to hundreds of individuals and among other phenomena had demonstrated that when two people look through the back windows, the head of one individual appeared to be very large, the head of the other to be very small. When the individuals reversed the windows they were looking through, the size of their heads appeared to the observer to change. But on this Sunday morning when my friend's wife was observing him and me, she said, "Well, Louis, your head is the same size as ever, but Hadley your head is very small." Then we changed the windows we were looking through and she said, "Louis, you're still the same, but Hadley you've become awfully large." Needless to say this remark made a shiver go up my spine and I asked her how she saw the room. It turned out that for her—unlike any other observer until then—the room had become somewhat distorted. In other words, she was using her husband—to whom she was particularly devoted—as her standard. She would not let him go. His nickname for her was "Honi" and we have dubbed this the "Honi phenomenon."

This observation was followed systematically in a series of experiments on married couples by Dr. Warren Wittreich. He found that if couples had been married less than a year there was a very definite tendency not to let the new marital partner distort as quickly or as much as was allowed by people who had been married for a considerable time (7). But, again, I hasten to add that it is not a simple matter of how long one has been married that determines how willing one is to distort the size or shape of one's marital partner! The original observation was made on a couple who were already grandparents. Preliminary investigation also seems to show that parents of young children will

not allow their children to distort as readily as will parents of older children.

We could continue at some length reporting experiments which seem to show that what we "perceive" is, as already emphasized, in large part our own creation and depends on the assumptions we bring to the particular occasion. We seem to give meaning and order to sensory impingements in terms of our own needs and purposes and this process of selection is actively creative.

SOCIAL CONSTANCIES AND SELF-CONSTANCY

It is clear that when we look for constancies in other people either as individuals or as members of a group a variety of complications is introduced. For when people are involved, as contrasted to inorganic objects or most other forms of life, we are dealing with purposes, with motives, with intentions which we have to take into account in our perceptual process—the purposes, motives and intentions of other people often difficult to understand. The purposes and intentions of these other people will, of course, change as conditions change; and they will change as behavior progresses from one goal to another. Other people's purposes will be affected by our purposes, just as our purposes will be affected by theirs.

It is by no means a quick and easy process, then, to endow the people with whom we participate in our interpersonal relations with constancies and repeatabilities that we can always rely on. And yet we must, of course, continue the attempt to do so, so that our own purposeful action will have a greater chance of bringing about the satisfying consequences we intended. So we try to pigeonhole people according to some role, status, or position. We create constancies concerning people and social situations. These provide us with certain consistent characteristics that will ease our interpretation and make our actions more effective so long as there is some correspondence between the attribution we make and the consequence we experience from it in our own action.

The "social constancies" we learn obviously involve the relationships between ourselves and others. So if any social constancy is to be operational, there must also be a

sense of "self-constancy." The two are interdependent. Since the human being necessarily derives so much of his value satisfaction from association with other human beings, his conception of his "self," his own "self-constancy" and "self-significance" is determined to a large extent by the significance he has to other people and the way they behave toward him. This point is, of course, a familiar one to the psychiatrist and has been eloquently illustrated in literature as, for example, in Shaw's *Pygmalion*.

But it seems to me of paramount importance in any discussion of perception and interpersonal relations that we should not slip into the error of positing an abstract "self" or "ego" that can somehow be isolated, pointed to, analyzed, or experienced apart from any social context. It is only through the life setting and the process of participation with others that meaning and continuity are given to the "self." If the constancy of "self" is upset, it becomes difficult for us to assess changes in our interpersonal relations and accommodate to them. We lose the compass that keeps us going in a direction. "We" are lost.

This does not mean in any sense that for self-constancy to be maintained there can be no development or growth. On the contrary, self-development and growth are themselves aspects of social constancy. But this development must, as the psychiatrist knows better than anyone, flow from form if it is to be recognized, if there is to be continuity, and if there is to be a standard for comparison. Obviously, each of us surrounds himself with anchoring points of one kind or another which help to maintain this self-constancy in the process of ceaseless change around us. In this connection I think, for example, of Konrad Lorenz' interpretation of why people like dogs. In his book *King Solomon's Ring*, he writes that we should "not lie to ourselves that we need the dog as a protection for our house. We *do* need him, but not as a watch-dog. I, at least in dreary foreign towns, have certainly stood in need of my dog's company and I have derived, from the mere fact of his existence, a great sense of inward security, such as one finds in a childhood memory or in the pros-

pect of the scenery of one's own home country, for me the Blue Danube, for you the White Cliffs of Dover. In the almost film-like flitting-by of modern life, a man needs something to tell him, from time to time, that he is still himself, and nothing can give him this assurance in so comforting a manner as the 'four feet trotting behind.'"

This interdependent problem of social constancy and self-constancy has been submitted to some preliminary investigation. For example, when a person is wearing a pair of aniseikonic spectacles, which greatly distort the shape of the environment when familiar monocular cues are ruled out, he will generally see another person as distorted if that person is standing in an environment which has itself already become distorted. With a certain pair of these spectacles, for example, an individual will be seen as leaning forward with the upper and lower half of his body distorted in length. Dr. Wittreich set up such a situation at the Naval Training Center at Bainbridge, Maryland to see what might happen when the relationship of the person who was doing the viewing and the person being viewed was altered. His subjects were 24 white male Navy recruits. They first observed an authority figure dressed up as a first class petty officer and, second, a non-authority figure dressed up in a white enlisted uniform with the marks of a recruit. Wittreich found that the authority figure did not distort nearly as much as the non-authority figure. In other words, the disciplinary training imposed in an organization that depends for effective functioning on the rigid acceptance of roles had produced a "constancy" which overpowered physiological changes in the optical system.

Another finding using the aniseikonic spectacles may be of interest to psychiatrists: namely, that a person tends to report much less distortion of his own image when he looks at himself in a full length mirror while wearing aniseikonic spectacles than he reports when he is looking at a stranger. When one looks at one's self, the changes that appear seem to be minor and detailed—for example, slight distortions in the hands or feet; when one looks at a stranger, there is the more general bodily distortion plus the

leaning one way or another, depending on the kind of spectacles used.

A subsequent study by Wittreich and one which I emphasize is only suggestive, was made comparing 21 subjects obtained from the patient roster of the neuro-psychiatric unit at the Bethesda Naval Hospital. When these disturbed individuals were wearing aniseikonic spectacles and saw their own image in the mirror, they tended to see the gross distortions that the "normal" population attributed to others; and, conversely, when the disturbed clinic population looked at others, they tended to see the more detailed and minor distortions which the "normal" population had seen in themselves. All I should like to conclude about this particular experiment so far is that there seems to be some difference between the normal individual and the clinical patient in the functional importance assigned to his bodily image; the patient may conceivably be operating in terms of a relatively fixed and homogeneous image of himself which does not alter readily with the demands of the environment.

PERCEPTUAL CHANGE

Laboratory experimentation as well as research in the field of opinion and attitude change seems to demonstrate beyond a shadow of a doubt that the major condition for a change in our perception, our attitudes or opinions is a frustration experienced in carrying out our purposes effectively because we are acting on the basis of assumptions that prove "wrong." For example, Dr. Kilpatrick has demonstrated that apparently the only way in which we can "learn" to see our distorted room distorted is to become frustrated with the assumption that the room is "square" in the process of trying to carry out some action in the room (8). It is clear that an "intellectual," "rational," or "logical" understanding of a situation is by no means sufficient to alter perception. The psychotherapist has taught us how successful reconditioning requires a therapy which simplifies goals so that their accomplishment can be assured through an individual's action as he experiences the successful consequences of his own behavior and thereby rebuilds his confidence in himself.

In this connection I recall a conversation I had in 1948 in Paris with an extremely intelligent woman who was at that time a staff member of the Soviet Embassy in Paris. We were at some social gathering and she began to ask me about American elections and the two-party system. She just couldn't understand it. She wasn't trying to be "smart" or supercilious. She was simply baffled. She couldn't "see" why we had to have 2 parties. For, obviously, one man was better than another and why wasn't he made President and kept as President as long as he proved to be the best man? It was a difficult argument for me to understand, just as my argument was impossible for her to understand. It was much more than a matter of opinion, stereotype or prejudice on either side. We were simply living in different reality worlds, actually experiencing entirely different significances in happenings which might appear to "an objective" "outside" observer to be the same for both of us.

Parenthetically, while one of the outstanding characteristics of man is often said to be his amazing capacity to learn, it seems to me that an equally outstanding characteristic is man's amazing capacity to "unlearn" which is, I think, not the exact opposite. Because man is not entirely a creature of habit, he has the fortunate ability to slough off what is no longer of use to him.

THE REALITY OF ABSTRACTIONS AND THE COMMONNESS OF PURPOSES

In order to ease our interpersonal relations and to increase the commonness of the significances we may attribute to the happenings around us, man has created abstractions in his attempt to bring order into disorder and to find more universal guides for living no matter what the unique and individual purposes and circumstances of an individual may be. Such abstractions are represented by our scientific formulations, our ethical, political, legal and religious systems. The abstractions can be recalled and repeated at will. They can be communicated. They are repeatable because they are static and have fixed characteristics.

The value of these abstractions for us in our interpersonal relations seems to be that

when the tangibles of our personal reality world break down, we can turn to the intangible—to the abstractions we have learned that have been created by others and have presumably proved useful to them. We can begin to check our own particular situation, possibly a frustrating one, against the abstraction and thereby, perhaps experience for ourselves what the abstraction is referring to. Only then will the abstraction become real for us. For when it does become functional for us in our own individual lives, it is real as a determinant of our experience and behavior.

I will close this discussion of perception and interpersonal relations with a story which seems to sum a good deal of what I have been talking about. The story concerns three baseball umpires who were discussing the problems of their profession. The first umpire said, "Some's balls and some's strikes and I calls 'em as they is." The second umpire said, "Some's balls and some's strikes

and I calls 'em as I sees 'em." While the third umpire said, "Some's balls and some's strikes but they ain't nothin' till I calls 'em."

EXPERIENCE WITH PHOTIC STIMULATION IN PSYCHIATRIC RESEARCH^{1, 2}

GEORGE A. ULETT, M.D.³

In a search for physiological factors underlying those mental disorders currently classified as "... without clearly defined physical cause ..." an intermittent photic stimulus has been used in conjunction with electroencephalographic recording. Such an investigative technique permits a study of the brain in action—responding to a stimulus—in contrast with investigations of the brain at rest. This approach has seemed promising for the study of behavioral disorders where symptoms may be the result of a dysfunctioning brain. (A discussion of preliminary work with this method(21) and a review of the recent literature(3) are available.)

Our initial observations had suggested that subjects, considered by psychological and psychiatric observation to show borderline adjustment or frank maladjustment, displayed a greater brain wave driving response when stimulated by frequencies of 20 to 30 f.p.s. than by frequencies under 20 f.p.s., and showed a marked harmonic response to stimulation in the 10 to 15 f.p.s. band. We pursued this lead with another study of 191 subjects(26). By utilizing an electronic brain wave analyser it was possible to quantify the electroencephalographic response of the subjects to flicker at 24 frequencies of light stimulation ranging from 3 to 30 f.p.s. The past and present history of symptoms suggesting anxiety or behavioral maladjustment of all subjects were studied and each

subject was given a rating of proneness to develop anxiety under stress. This "anxiety-proneness" rating was found to be significantly correlated with 1:1 and/or harmonic response to flashing light at frequencies above the alpha range. This finding seemed in accord with reports in the literature of an increased amount of fast activity in the basic resting electroencephalographic patterns of patients with anxiety reactions. It appeared that a latent tendency to such fast activity was indicated by the induction of a strong driving response by the appropriate fast frequency of photic stimulation. In similar thought, the evocation of a paroxysmal response at a subharmonic of the light stimulus in some epileptics has been reported as indicative of a latent tendency to slow activity by Mundy-Castle(15). A second sample of 117 patients however, was run in like fashion and although the photic driving response at both high and low frequencies tended to be greater among the anxiety prone, the discriminating value of the test in this sample now lacked statistical significance. The relationship of cortical response to photic stimulation and anxiety is at this time an unsettled question.

In both of the above studied groups however, there was seen, in anxiety-prone individuals, a significantly greater amount of subjective dysphoria, visceral sensations and/or anxiety during exposure to photic stimulation. This, in our experience, is not an unusual occurrence during such stimulation(20) and may, in some persons, seem to reactivate symptoms, often of a neurotic nature, that have been experienced in the past. The use of an intermittent photic stimulus as a provocative test for such sensations in the screening of military personnel for the selection of anxiety-prone subjects was explored with some success in our control population. Further study and evaluation of these observations is presently being undertaken on a group of some 1,500 air cadets whose subsequent careers and exposure to stress in military situations can be followed(18).

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² The studies mentioned in this report were completed under Air Force Contracts 33(638)-1384 and 18(600) 627 of a series under R and D Project 21-37-062, Division of Psychiatric Screening of Flying Personnel, Department of Clinical Psychology, U. S. Air Force School of Aviation Medicine, and through research grants from the National Institute of Mental Health of the National Institutes of Health, U. S. Public Health Service.

³ Department of neurology and psychiatry, Washington University School of Medicine, and research laboratories of Malcolm Bliss Psychiatric Hospital, St. Louis, Mo.

The use of field performance was felt to be the only practicable validating criterion of the selective value of this method for use in a military screening battery. This conclusion was reached when, in an attempt to increase the validity of our psychiatric-psychologic anxiety-proneness rating, we introduced in place of one, two experienced board certified clinical psychiatrists only to find that their agreement upon both anxiety-proneness and maladjustment ratings in a control population was very poor(6).

Other investigators have explored this area of relating photic stimulation to personality variables. Blum(1) reported an EEG response to photic stimulation that was characteristic of schizophrenics and patients with organic brain syndrome that was not seen in "normal" controls. Shagass(19) used the EEG response to photic stimulation to differentiate between patients showing either mainly anxiety symptoms or depression. He compared the response to 15 and 10 flashes per second and found a greater response at the faster frequency in those subjects with anxiety. Further observations in his laboratory suggested that in persons repeatedly tested, the driving response would fluctuate from day to day with changes in mood and that the driving response at 15 flashes per second was highest during times of anxiety or annoyance. Such fluctuation of the driving response with transient mood change was in the opposite direction to that found in our studies where a test situation (23) that was frustrating, annoying and often anxiety provoking, produced in most subjects a temporary decrease in the driving reaction to 14 flashes per second which increased again when the experimental anxiety producing stimulus was withdrawn. The differences were not clearly seen in all individuals however, and the experimental situation could not be said to produce purely an anxiety response in all persons.

There is certainly a need for more basic knowledge regarding this phenomenon of photic driving. There has, for example, been presented no careful profile analysis of the photic driving response taken over a period of weeks or months to note the consistency of response at different frequencies. Such a study is basic to the selection of the best

stimulus frequencies for correlative studies of fluctuations in driving with mood or psychic phenomena. To begin work in this area we have plotted the electronically analysed EEG driving profiles of 171 subjects stimulated at 24 different flicker frequencies. The median driving curve and first and third quartile curves for the group are shown (Fig. 1). The marked difference among individuals is shown by the wide range indicated here.

To study the stability of the driving measure we are repeating the procedure on a selected group of 50 subjects at spaced intervals two to three times a year for a 3-year period. Preliminary analysis of data on 12 subjects reveals that the shape of the driving curve is generally consistent for one individual from time to time with an average intraclass correlation of .67 with the range of correlations from .10-.84 for the 3 trials. However the amount of total driving (*i.e.*, "energy") of the response is more variable, showing an intraclass correlation of only .46. Both of these correlations would occur by chance less than 1 time in 100. The curves of two subjects indicating the driving profile as seen on 3 different occasions are shown as an example (Figs. 2 and 3). Figure 4 illustrates a subject in whom both profile and amount of response varied over the 3 trials. A complete report of this work is in progress.

In an earlier study(12) we compared and found relationships between color, movement and FK responses on the Rorschach and similar subjectively experienced color, movement and depth or vista sensations experienced during exposure to intermittent photic stimulation. A relationship was also found between simple and limited descriptions of the flicker induced sensations and a Rorschach perceptual style that has been designated as suggestive of rigidity in the personality structure(8).

Specific ability of certain frequencies to produce both physiological and psychological phenomena and to reproduce clinical symptomatology is, although unexplained, of great interest. Lovett Doust(11) has shown that shifts in blood oxygen saturation tend to occur at certain specific frequencies of photic stimulation. Walter(30) earlier described, and we have noted time and again, that for

MEDIAN DRIVING RESPONSE TO PHOTIC STIMULATION WITH FIRST AND THIRD QUARTILE POINTS.

FIG. 1.—Curves illustrating the median driving response together with the first and third quartile points of 171 subjects tested at 24 frequencies of photic stimulation. The data are based on electronic EEG analyser summations of the Rt. Parieto-occipital lead combinations during 40 consecutive seconds of stimulation at each frequency.

FIG. 2.—Curves made from electronically analysed Rt. Parieto-occipital EEG recording data illustrating the profile of EEG driving response to stimulation at each of 24 different frequencies of light stimulus presented to control subject #59 on 3 separate occasions. This subject was a male student, 22 years of age with a normal resting EEG and no personal or family history of neuropsychiatric disturbance.

FIG. 3.—Curves made from electronically analysed Rt. Parieto-occipital EEG recording data illustrating the profile of EEG driving response to stimulation at each of 24 different frequencies of light stimulus presented to control subject #71 on 3 separate occasions. This subject was a male student 22 years of age with a normal resting EEG. The only positive item in his neuropsychiatric examination was a possible febrile convulsion in childhood.

some individuals subjective dysphoria, myoclonus or paroxysmal activity in the EEG would occur only, or mainly, at certain frequencies, and at times to a lesser degree at related harmonics or subharmonics of such frequencies. Mundy-Castle(16) reported a case in which photic stimulation at certain critical frequencies produced both irregular slow bursts in the EEG and visual hallucinations related to past experiences. Following a course of insulin coma treatments photic stimulation elicited neither the hallucinations nor the abnormal EEG changes.

Similarly a specificity of stimulus frequency or elicitation of response by frequencies within a limited band has been seen in selected epileptics. Those individuals who

do not have evident convulsive disorder, but whose EEG can be induced to show paroxysmal activity at certain frequencies of photic stimulation, raise speculation regarding a lowered convulsive threshold and predisposition to clinical seizures. Such photically induced changes have been reported in subjects without personal or family history or clinical findings that would suggest either psychiatric or convulsive disorder(28). Buchthal and Lennox(2) found photic stimulation of some use in detecting latent convulsive disorder but felt that the procedure was less useful in this regard than Metrazol activation. We have seen both EEG and clinical paroxysms induced in subjects by light alone, when the neurological examination and personal and

FIG. 4.—Curves made from electronically analysed Rt. Parieto-occipital EEG recording data illustrating the profile of EEG driving response to stimulation at each of 24 different frequencies of light stimulus presented to control subject #12 on 3 separate occasions. The subject was a male student, 22 years of age, with a normal resting EEG. The only positive item in his neuropsychiatric examination was a questionable concussion during college boxing.

family history were negative for convulsive and neuropsychiatric disorder. This has been puzzling and poses the question whether sensitivity to intermittent light stimulus (*i.e.*, production of paroxysmal EEG activity) may indicate a low threshold for convulsive seizures in some and in others indicate a physiologic or sensory lability that might relate to behavior disturbance or even susceptibility to psychogenic disorder. We searched within our normal control group for indications that EEG activation might, of itself, relate to a positive personal or family history or to symptoms of neuropsychiatric disorder but in this group, studied by careful interview and neurological examination, the search does not look promising.

Studies by Leiberman(9) et al., Gastaut (4), Hill(7) and others have implied that a lowered photo-pharmacologic convulsive threshold exists in schizophrenics and possibly in certain cases of hysteria and that it may indicate some common, sensitive diencephalic neural mechanism that responds to the photic stimulus similarly in both groups of patients. A careful review of these and other studies reveals a considerable problem in the interpretation of an endpoint for convulsive threshold when induced by means of

photic stimulation following the injection of small amounts of a convulsant drug(24). It seemed to us that before measuring convulsive thresholds in a carefully defined group of schizophrenics, some attention should be given to methodology. Hence we have investigated and reported a method of threshold measurement using hexazole and photic stimulation that seems to have a high reliability and validity. A study is now in progress in our laboratory using this method to compare the convulsive threshold of carefully selected schizophrenics and a matched control group. Although the results are as yet incomplete, no difference has so far been found between the two groups. We have no ready explanation of why our findings in this area should differ from those of other workers although we would point out that alterations in metabolism can produce a marked change in sensitivity to photic stimulation. (Fig. 5 shows samples of an EEG from a control subject with a normal basic EEG. In the first instance he was subjected to photic stimulation after 30 hours of sleep deprivation and when he had been without food for 12 hours. At this time he showed marked clinical myoclonus and paroxysmal activity in the EEG. On the same day fol-

FIG. 5.—Samples of EEG recording from 22 year old student control with normal resting EEG. The first record was made at 11:00 a.m. following a night without sleep and after a 12 hour fast. The marked EEG activation shown was accompanied by generalized myoclonus. The second record was taken approximately 4 hours later after the subject had had a good meal and 3 hours sleep. At this time neither clinical nor EEG activation occurred.

lowing 3 hours of sleep and a good meal he no longer demonstrated clinical activation and showed but little EEG change to photic stimulation.) One might wonder whether such changes in metabolic conditions, not uncommon among schizophrenic patients, could account for some of the lower convulsive thresholds reported in the literature.

The ease with which an intermittent photic stimulus could induce paroxysmal activity in the brain of any subject after sensitization by a convulsant drug (i.e., hexazole) led to its use as a new type of shock treatment (photo-shock) (Gastaut and Cossa(5), O'Flannagan(17) and Ulett(25)). It seemed to us that such a method might permit an evaluation of subconvulsive treatments as compared to convulsive treatments(22), hence a matched control study was completed (29). The results of this study concerning the value of photo-subconvulsive treatment are in agreement with those of Montagu's(13) carefully controlled investigation of subconvulsive electroshock. Results by Montagu and our own controlled study indicate that subconvulsive treatments are without value in the therapy of either psychoneurotic (anxiety) or psychotic disorders (depression). Convulsive photo-shock on the other hand appeared to be more efficacious than routine electroconvulsive therapy. We found photo-shock to produce a gentler seizure of gradual onset, to create less confusion and to show,

in a 6-month follow-up, a more lasting recovery.

Another use of intermittent flashing light is as a tagged stimulus in the search for neurophysiological processes underlying learning and more particularly conditioning. Early work from Russia(10) and from our own laboratory seems to indicate that in the learning process there is a phase where the brain may beat in the rhythm of the conditioning stimulus (light) at a time when the light stimulus has been turned off. The evidence for this is at the moment tenuous but it is strengthened by the work of Morrell and Jasper(14) who found in monkeys, when photic stimulation was paired with a steady sound stimulus, that for a limited period of time the sound alone could induce the driving response. Much work remains to be done in this interesting area.

SUMMARY

Intermittent photic stimulation has been of value in psychiatric research in a number of areas which include: (1) the development of screening techniques based upon the EEG driving response and subjective responses to photic stimulation; (2) correlated studies of photic stimulation with psychological tests; (3) studies relating driving response to clinical symptomatology; (4) use in provoking paroxysmal or psychiatric symptoms;

(5) use of photic stimulation, together with a convulsant drug to study differences in convulsive thresholds among patients of various diagnostic groups; (6) as a treatment method in photo-shock, and (7) for studies of the neurophysiology of learning.

METHODS EMPLOYED AND RESULTS OBTAINED IN PSYCHIATRIC STUDIES WITH NEW DRUGS ACTING ON THE BRAIN STEM¹

F. A. MIELKE

The clinical investigations with pharmacological agents which we have been conducting at the Burghoelzli Clinic, Zurich, extend back over 2½ years. During this time, we have treated several hundred patients and studied their reactions from the therapeutic and scientific aspects. The following new drugs proved themselves clinically applicable: (1) Reserpine (Serpasil), (2) Chlorpromazine (Largactil), (3) Covatin (P-butylmercaptobenzhydryl-8-dimethylamino-ethyl sulphide) as hydrochloride (derived from the antihistamine Benadryl).

To begin with, some details should be given as to how we assessed the results obtained. Under the conditions prevailing in our clinic, it was found that the procedure yielding the most satisfying results was to entrust the testing of each different drug to the same doctor; he initiates the treatment himself, keeps the patients under surveillance, and discusses the details of his cases with other colleagues in the clinic, particularly those responsible for the various wards. This method has several obvious advantages:

1. It makes it easier to obtain an over-all picture of the patients undergoing treatment and to compare the various forms which the process of the disease takes in each individual case.

2. The psychological and somatic findings are recorded and followed up by one and the same doctor.

3. This same doctor studies the course of the disease from the very beginning to the catamnesis.

4. When the findings are assembled and the statistics analyzed, the doctor who has completed a series of investigations in this manner has a good and clear personal impression of every patient he has treated. This appreciably simplifies the task of assessing precisely how a psychosis has responded to a given drug—a task which is often far

from easy; it also ensures more reliable evaluation of the results.

5. In many cases treatment is an ordeal which has, as it were, to be shared with the patient—either because he is completely lacking in understanding at the start or because the side-effects of the drug, such as tremor, may begin to undermine his confidence in the therapy. Here, in the majority of cases, we were able to exploit the phenomenon of “transference” between patient and doctor.

6. Where treatment is conducted in this systematic fashion, the nursing staff has a better and more clear-cut conception of the character and purposes of the therapy. If a ward attendant requires instructions or an example to guide him, he knows to whom he can turn.

The problems which have chiefly interested us so far, and have, in one way or another determined the character of our studies, are the following:

1. To what extent and in what way do the new drugs improve the symptoms of psychotic, neurotic, and psychopathic patients or disorders of organic origin? (Disorders treated by us to date include schizophrenia, manic and depressive states, psychopathic reactions, acute and chronic organic syndrome associated with cerebral arteriosclerosis and alcoholism, mental deficiency and organic syndromes associated with epilepsy, senility and Huntington's chorea.)

2. What is the relationship between the therapeutic effect and the concomitant somatic symptoms produced by these drugs? Are the somatic and psychological effects interdependent or are the accompanying symptoms, especially those of a neurological nature, dysfunctions which must be accepted as the price to be paid for the benefits of the therapy?

3. Do these new agents produce a long-term change in the course of psychotic processes, especially those of schizophrenia? Are there any connections between the success or failure of the treatment and the pa-

¹ From the Burghoelzli Psychiatric Clinic, University of Zurich, Zurich, Switzerland, (Director: Prof. M. Bleuler).

tient's prepsychotic personality, his physique, and heredity? In other words: is the therapy symptomatic or causal?

It was with these same problems in mind that M. Bleuler⁽¹⁾ some 15 years ago, examined "the nature of schizophrenia remissions following shock therapy." His pioneer study served as a guide to our present investigations. Accordingly, in attempting to assess the long-term results of the treatment administered to our schizophrenic patients, we have also distinguished between the following categories, corresponding to the course of the diseases: (1) acute or chronic onset; (1) simple or cyclic course; (3) terminal stage reached prior to medicamentous therapy.

On this basis, we have drawn up the following groups: (1) Deterioration (Dementia²) following: (a) an acute course, (b) a chronic course, (c) a cyclic course; (2) residual states (Defective²) following: (a) an acute course, (b) a chronic course, (c) a cyclic course; (3) previous recoveries (good or complete remission): following a cyclic course; (4) atypical courses; (5) extremely acute schizophrenia; (6) leucotomised patients with subsequent relapse.

In no instance did we have any particular difficulty in fitting our cases into the above pattern. This classification according to course of disease offers several advantages when assessing the results of treatment:

1. It provides a guide to the prognosis and enables one to recognize quite clearly—irrespective of the symptoms displayed—which pathological process one is treating. In this way, it is at least to some extent possible for the strict standards of methodical drug-testing as practised in internal medicine, e.g., in connection with the treatment of hypertension (Martini), to be applied to the complex and equivocal field of schizophrenia.

2. When describing the results obtained, it serves as a clear means by which to survey and compare the cases treated. It also marks a step toward an international standardization of the conception of schizophrenia, which at present is still variously interpreted.

We very soon learned from experience that the indications for the different drugs could not be determined on the basis of the diag-

nosis or by reference to the system of schizophrenia classification that has just been outlined. Instead, it is the clinical picture of the psychosis and the principal symptoms which afford the main guide. Accordingly, we also adopted a scheme for differentiating between the various symptoms, about which, however, it is not proposed to say anything further here.

For the sake of convenience, we grade our therapeutic results in the following categories: (1) No appreciable psychic effect either during or after treatment. Temporary sedation at times, as a direct sequel to individual doses. (2) Marked decrease in schizophrenic symptoms. Patient much easier for the nursing staff to handle, and able to participate in the simplest forms of occupational therapy. (3) Satisfactory improvement on an inpatient basis. Patient co-operates well, displays some independent initiative, and can be kept in a quiet or open ward. (4) "Social remissions" and "residual states." Patient capable of earning a living in a simple routine occupation. Schizophrenic symptoms, though still present, are slight and such as to arouse little attention in the casual observer, but there is clear psychiatric evidence of defective personality. (5) Good remission. Patient fit for work. No recognizable psychotic symptoms, but a slight change in personality. (6) Complete remission. No change either in personality or performance.

Table 1 gives the general appearance of an assessment chart such as is drawn up for each patient.

And now for some details concerning the results we have so far obtained:

Covatin.—This has hitherto been described in the literature as a sedative with spasmolytic but no hypnotic properties. No toxic effects were observed with this drug in response to daily doses of 150 mg. for 150 days or 300 mg. for 50 days. Given alone, Covatin had no significant effect on our psychiatric patients. At present, we are using this drug only for initial treatment and always in combination with chlorpromazine. This combination does not seem to influence the patient's impulses, initiative, and psychomotor system, but does modify primarily his low spirits and melancholy. Hence, we have already achieved several encouraging successes with this com-

² Classification according to Manfred Bleuler.

atmosphere of calm, security, and understanding in the ward in question. Throughout the entire course of treatment, we study each patient's particular problems. Where the patient claims to hear voices, reports imaginary experiences, or suffers from delusions, we always begin by accepting these notions as reality; we discuss them with the patient, and promise to get to the bottom of his problem or protect him from imagined dangers. In this connection we also frequently make use of interpretation by "transference," as described by Rosen and Benedetti.

As the drug takes effect, the patients themselves begin to regard the doctor and the nursing staff as healers and helpers—as allies in their struggle against the psychotic forces. Hence, the words and explanations used by the doctors and staff tend to assume great importance as in counteracting the patient's psychotic ideas and impulses; the very fact that a patient can, if only to some extent, believe in what they say is a sign that he is beginning to gain insight. Thus, provided one understands how to make profitable use of their time, the patients need not be left to idle away their days in futile inactivity.

Direct analysis of an individual schizophrenic patient involves a considerable sacrifice of time and effort for the doctor, and for this reason it resorted to only in exceptional cases. Where reserpine treatment is given, however, it is possible to achieve an all-around psychotherapeutic effect.

After an average of 14-21 days, we allow the patients to get up, whereupon we gradually introduce them to occupational therapy while at the same time keeping a watchful eye on their mental health and treating them with Serpasil tablets.

In order to bridge over a certain phase occurring during convalescence, we often administer Ritalin or Dexedrine, preferably spansules, either after the reserpine course has been completed or while the patient is being adjusted to a maintenance dosage of reserpine. This combined treatment with Ritalin or Dexedrine is especially indicated in cases of depression; here very accurate dosage is called for, so as to prevent the patient from lapsing into increasing lethargy.

To revert to the questions mentioned earlier, which our studies were designed to

TABLE 2

RESULTS AFTER A SINGLE COURSE OF RESERPINE THERAPY—194 PATIENTS

* One discharged patient died.

answer, the results obtained with Serpasil are presented in Table 2. The catamnesis of 98 of these patients presented after 12 months of therapy (in contrast to the results one month after treatment) appears in Table 3.

Deteriorated patients and those with unsuccessful leucotomies are not included in these statistics, since it is not possible to assess their cases merely on the basis of a single course of reserpine therapy. As a rule, it is only after they have undergone several long courses of treatment or long-term medication that patients respond with an improvement to categories 2 or 3. With this method of treatment, we succeeded in rescuing a number of hopelessly stranded cases among the chronic patients in the clinic. If conducted in a more intensive and persistent manner, these new courses of treatment may

TABLE 3

* Two discharged patients died.

well help schizophrenic patients on the road to a form of existence which, although obliging them to remain in a mental institution, is nevertheless better than that to which they might otherwise have been condemned.

As yet, we are not in a position to judge what effect prolonged maintenance doses, given perhaps for years at a time, will have on mildly defective schizophrenics. In cases in which a good "social" remission has been achieved, it is doubtful in most instances whether the patient will take the drug regularly, although a single daily dose should prove sufficient. On the other hand, we know of several cases already, in which relapse and, for example, exacerbations in paranoiac subjects have been successfully nipped in the bud with reserpine by the patient's own family doctor.

Bearing in mind the system we have adopted for classifying these mental disorders, according to the course taken by the disease, the problem of employing prolonged treatment with maintenance doses raises, among other points, the following specific questions: (1) In cases where the disease follows a cyclic course, and especially where acute episodes follow in rapid succession, is a drug which acts on the brain stem capable of prolonging the remissions or preventing relapse altogether? (2) Is it possible, by means of prolonged medication (and ambulatory psychotherapeutic treatment), to raise the patient out of a defective state, especially in cases where the disease assumes a cyclic course and a certain degree of deficiency remains?

This raises the whole question of the problems connected with long-term therapy and with the prevention of acute episodes in the course of the disease.

Further results obtained by us cannot be given here in detail, but may be presented in summary form:

1. In 84% of our cases, a single course of reserpine—given in a dosage corresponding to the severity of the symptoms—was effective in influencing the process of the disease *for the present*. The therapeutic result achieved in such instances could be classified as ranging between "satisfactory improvement on an inpatient basis" to "complete remission"—depending on the severity of the patient's psychotic condition.

2. The result of reserpine therapy depends upon the stage at which the treatment is initiated (dementia, defectiveness), upon whether the patient has hitherto recovered from cyclic episodes, and upon the severity of the individual symptoms.

3. The *immediate* success of a single reserpine treatment is independent of the prepsychotic personality. On the other hand, the patients who are still cured 1 year after the end of treatment showed a prepsychotic condition which was 49% healthier than the other patients. Relationship between success and failure of the therapy and physique or heredity has not been found.

4. The treatment has no long-term effect on the course of the various schizophrenic processes. In every case, the schizophrenic process one year after treatment runs the same course as before. The only exceptions to this rule are patients with a particularly favorable prognosis, *i.e.*, those suffering merely from a mild defect and, even then, only if the disease displays a cyclic pattern.

5. In cases involving acute schizophrenia and cyclic patterns, in which every acute episode has hitherto been followed by recovery, the over-all result achieved with reserpine corresponds to the response elicited with the types of symptomatic therapy previously in common use. From the biological aspect, the "cures" effected with these latter forms of treatment resemble spontaneous remissions.

6. The concomitant somatic effects, and particularly the extrapyramidal symptoms, are not essential prerequisites for the drug's psychological action, nor is there any causal connection between such somatic effects and its psychic action. It would be more correct to consider them as regulatory disturbances, which occur regardless of either the size of the dosage administered or the initial state of the patient's autonomic nervous system and brain stem.

To sum up, then, we would describe reserpine as a very effective drug for the *symptomatic treatment* of psychiatric cases. In comparison with previous forms of therapy, it has several advantages, among which in particular is the fact that it involves no risks when given in appropriate doses, and that it is relatively easy to handle; one of its principal merits, moreover, is that it offers every

possibility and encouragement for psychotherapy and occupational therapy.

Chlorpromazine.—This drug bears a very close resemblance to reserpine as regards its psychic effects. In contrast to reserpine, it occasionally has a mild euphoric effect on depressed patients. This would appear to be an advantage when treating some cases of depression. The significance of chlorpromazine is generally recognized today and reports on clinic experiences amount to more than a thousand articles at present. If I have reported mostly on our experiences with reserpine, it was done with the intention of discussing the principles of clinical methodology in connection with drug therapies. Therefore, what was said about reserpine, applies generally to chlorpromazine in the same fashion. K. Ernst (4), a member of our staff, reported in 1953 about the effects of chlorpromazine after trying it out on himself. Since then, several hundred patients have been treated with this drug.

There are certain patients who respond admirably and unfailingly only to the one or the other of these 2 drugs, even when the treatment is given repeatedly. In some cases, this is obviously due to differences in the patients' physical reaction, whereas in other cases it is impossible to discover the reason. We have hitherto assumed that such differences in the effect of these drugs are determined by the state of the patient's autonomic nervous system at the outset of treatment. To investigate this problem is a task of practical significance for the future. The chief differences between reserpine and chlorpromazine lie in their somatic effects. It may even be said that the difference in their somatic effects corresponds to the chemical difference in their structural formulas, whereas, curiously enough, their psychic effects are almost identical—assuming, of course, that they are given in equivalent dosages. For our patients, we found that about 10 mg. reserpine were equivalent to 300-400 mg. chlorpromazine. The question as to which of the 2 drugs should be used must be decided mainly in the light of the patient's physical case history and physical condition, as well as his individual reaction.

The progress which these new drugs acting on the brain stem have wrought in the

treatment of psychiatric cases is obvious. They represent the fulfillment of a desire that has been felt for many years—the desire for adequately effective drugs with a damping effect on the autonomic nervous system. Their introduction not only constitutes a welcome addition to the forms of treatment hitherto available for use in mental institutions, but also provides a powerful stimulus for those whose mission it is to tend the sick in mind. At the same time, the appearance of these new drugs has revived interest in many aspects of the problem of mental disease.

SUMMARY

The method and results of treatment with reserpine, chlorpromazine, and Covatin are reported. Also emphasized are the expediency of a semidarkened ward and the patient's accessibility to early psychotherapeutic contact. With chronic cases, the knowledge of the spontaneous course of the disease is the foundation of our appraisals of the therapeutic results. Categorization of patients is discussed according to the course of their illnesses before treatment. Results of therapy are further broken down into 6 degrees of improvement. Cases of schizophrenia treated by reserpine are used as an example for the manner in which pharmacological treatment affects only the temporary disease process. Follow-up studies of 194 patients mainly show that the treatment has no long-term effect on the course of the various schizophrenic processes. In every case, the schizophrenic process 1 year after treatment runs the same course as before.

TRANSORBITAL LEUCOTOMY IN NONINSTITUTIONAL CASES

ABRAHAM GARDNER, M. D.¹

INTRODUCTION

Transorbital leucotomy was developed in the course of search for refinement of the standard or prefrontal lobotomy. Walter Freeman elaborated the technique in its present form, basing his procedure on work by Fiamberti (1).

I have been using this method of psychosurgery since 1949. The patients in the various series reported in other papers, mostly by Freeman, were a mixture of institutional and noninstitutional cases. Those in this report came almost entirely from private practice and there are, therefore, certain interesting observations to be noted.

Of the various types of psychosurgical procedures none has proven to be simpler or safer than transorbital leucotomy. It has been pointed out before (1, 2, 3), and this author agrees, that the psychiatrist who makes an adequate study of the surgical anatomy and the technique of this operation can readily qualify for its use. This is because of its comparative safety and the inherent simplicity of the technique. In our series the operative mortality rate to date is 1.2%.

TECHNIQUE

The operative technique is as follows: One hour before operation the patient is given morphine sulphate gr. 1/6 and atropine sulphate 1/100 subcutaneously. The anesthetic agent is Sodium Pentothal given intravenously.

The instruments are the transorbital leucotomes especially designed by Freeman. The point of the leucotome is inserted beneath the raised upper eyelid at a distance of 3 centimeters from the midline, in a plane parallel with the bony ridge of the nose. It is caused to penetrate the superior conjunctival fornix and rested against the high point of the orbital roof. It is then tapped gently in to a depth of 5 centimeters and the handle is drawn laterally to the outer rim of the

orbit. The leucotome is then returned to the starting position and tapped in another 2 centimeters to a total depth of 7 centimeters. The handle is then drawn mesially to the ala of the nose, thence back to the starting position and then upward against the superior rim of the orbit. Here sufficient pressure is exerted to cause cracking of the edges of the bone at the point of penetration through the orbital roof. This allows for severance of some of the nerve fibers which overlie the orbital roof. The instrument is then withdrawn and a pressure bandage is applied and left in place for 20 to 30 minutes. This technique is carried out bilaterally.

The routine postoperative orders are as follows: (1) Blood pressure and pulse are taken every hour until the patient is fully awake. (2) Crysticillin, 300,000 units, is given intramuscularly stat. (3) Sulfadiazine, gm. 1.0, by mouth, every 4 hours for 24 hours. (4) Aspirin, grains 5, by mouth, every 4 hours if needed for headache or pain. (5) Ice-cold compresses are applied to the eyes continuously through the first 24 hours after surgery. (6) Warm boric solution compresses to the eyes continuously throughout the second 24 hours. (7) Report any unusual trend in blood pressure, pulse, temperature or state of consciousness. (8) Report immediately any convulsions and be prepared to administer sodium luminal, grains 5, intramuscularly. (9) Fluids and diet as tolerated. (10) Patient to remain in bed during the first 24 hours and then is allowed up and about, *ad lib*.

The patients usually were discharged home 2 days after operation.

Thus it appears quite clear that this procedure, in the hands of psychiatrists trained in its use, becomes more readily accessible for the patients in whom it is indicated. Also of much importance is the fact that is to be done by the doctors who take the responsibility of recommending it.

All the cases in this series were operated in a small community general hospital and no difficulty in their management was encountered. This, plus above-described technique

¹ Address: 190 Ocean St., Lynn, Mass.

and aftercare, emphasizes quite strongly that the procedure is suitable for use in the general hospital.

There remains the question of evidence that this operation is worth while doing. This, it is hoped, is shown in the evaluation of the data herein presented.

CASE MATERIAL

The patients chosen for the operation were those whose illnesses were chronic, severe and disabling. All had failed to respond adequately to various forms of more conservative therapy.

Emphasis in the selection of patients was placed on the prominence of tension, fear, agitation and depression; *i.e.*, the "tortured self-concern" in their symptomatology. In the schizophrenic patients special attention was given to the intensity of emotional tone still remaining. The group of psychoneuroses was made up of patients whose illness was of very long duration and who had true disability or incapacity.

The 115 cases herein summarized have been followed for 1 to 6 years with an average of $3\frac{1}{2}$ years. The only criterion of selection for evaluation was adequate follow-up.

The average mortality as reported in other series is 1.7% to 1.8%. In our entire series to date the rate is 1.2%. There were no complications of major significance and, of the few minor complications, none persisted longer than 4 days postoperatively. These consisted, in 2 patients, of inertia, lasting 2 days in one and 4 days in the other. Another patient developed an acute hallucinatory reaction with confusion a few hours after operation and this persisted 3 days before clearing. There were no personality changes, "vegetable reactions," loss of skills or inhibitions, or impairment of intellectual level, so far as could be observed. There were no postoperative epilepsies and no patients showed memory loss.

Results were evaluated on the basis of easing of symptoms, economic, social and recreational readjustment. Those with full remission of symptoms and good adjustments otherwise were classed as "remissions." Those with good adjustments but who had mild residual symptoms were classed as "improved," and the remaining cases as "failed."

The schizophrenic group totaled 40 cases: 9 schizo-affective, 12 paranoid, 13 catatonic, 1 hebephrenic, 1 juvenile and 4 type undetermined. The average duration of illness for the whole group was 6 years and the average follow-up after operation 4 years. There were 15 "remission," 12 "improved," and 13 considered as "failed."

In the group of affective disorders were 11 patients: 4 manics of whom 3 were "remissions" and 1 "failed," 1 hypomanic who attained a "remission," and 6 involution reactions of whom 4 were "remissions" and 2 "improved." The average duration of illness in this group was 9 years and the average follow-up 3 years.

In the group of psychoneuroses there were 51 patients. The average duration of illness was 15 years and the average follow-up 3 years. There were 34 cases of psychoneurosis, mixed types, of whom 15 were "remissions," 17 "improved," and 2 "failed." Of the 14 chronic anxiety reactions 8 were "remissions," 5 "improved," and 1 "failed." There were also 2 obsessive compulsive reactions, one a "remission" and one "improved." There was one case of neurasthenia which resulted in a "remission."

In a group of miscellaneous disorders there were 5 patients who were operated for intractable pain and suffering syndromes, 1 senile paranoid reaction, 2 senile depressions, 3 paranoid states, 1 psychosis with epilepsy, and 1 psychosis with mental deficiency. Of this group 5 attained "remission," 3 "improved," and 5 "failed." Four of the 5 who had intractable pain and suffering obtained excellent results. The 2 patients, one psychosis with epilepsy and one psychosis with mental deficiency, improved as to their psychoses, and that was the aim of the operation. The 3 with senile reactions did not improve. Table 1 gives a summary of all cases.

TABLE 1

SUMMARY OF ALL CASES

Diagnosis	No. of cases	Remissions	Improved	Failed

Affective disorders.	11	73	18	9
Psychoneuroses	51	49	45	6
Miscellaneous	13	38	24	38
Totals	115	44%	36%	20%

DISCUSSION

In general, the schizophrenics fulfilled the usual criteria of chronicity and disability as regards selection of cases for surgery. They did not show the characteristics of being "institutionalized," and in this regard were therefore less severe and regressed than similar groups in other series. Our results in this group are comparable to those reported by others (1, 2, 3, 6, 8, 10, 11).

Our most impressive results were found in the group of psychoneuroses. This is the largest group in the series and for the most part the illnesses were of the longest duration. In most instances their reactions to surgery were quite dramatic. It was common to observe marked alleviation or total disappearance of symptoms within one to two hours after operation, or about the time needed to waken fully from the medication and anesthesia. The great majority of those who responded well to the procedure showed their improvement in the first 24 hours. The usual hospital stay was two days after surgery. Within one to two weeks these patients were able to return to their regular activities of work and social and recreational pursuits. Some waited for the peri-orbital swelling and ecchymosis to clear enough so that they would not attract too much attention. Others simply wore dark glasses to mask the "black eyes" and some were back at their regular pursuits as early as 4 days after operation. This was true of all groups, not just the psychoneuroses.

The psychoneurotic patients had been struggling for years without much success to maintain a reasonable adjustment. They had eventually become truly disabled and had failed to respond adequately to other therapies. They were often receiving nothing more than symptomatic medication and had come to feel they were burdens to themselves and others. Such cases are encountered quite commonly and are often distressing to the physician as well. It is our opinion that such patients, after careful screening, should be considered for transorbital leucotomy. The risk is small, the response is frequently immediate and dramatic and the results are excellent in a very satisfactory percentage of cases. It is interesting to note that these patients, when exposed to strong stresses subsequent to operation, responded in an average manner. This would suggest that

the surgery had served to relieve them sufficiently of their tensions, fears, etc., but without producing indifference or inability to react emotionally.

In a period of over two years of extensive experience with tranquilizing and ataractic drugs, I have seen no convincing evidence that these drugs have made psychosurgery obsolete. They are valuable in treatment of psychiatric problems and should be given full trial before resorting to surgery but it should be recognized that they are not yet proven specifics, curatives, or productive of "medical lobotomies."

SUMMARY AND CONCLUSIONS

Results in 115 cases of transorbital leucotomy of noninstitutional patients are reported. The author believes that this is an excellent technique for treatment of selected cases from private practice, as well as such institutional cases reported by others.

Studies of the psychoneurotic group are of particular interest and indicate another method of management of a very common and difficult problem.

Results in those patients operated for relief of intractable pain and suffering suggest that this procedure is effective and among the least drastic of surgical measures.

Several patients who had secondary dependency on narcotics, barbiturates, and alcoholic beverages obtained relief from these dependencies along with relief from the underlying disorders and none showed any withdrawal symptoms.

CLINICAL EVALUATION OF PACATAL¹

PAUL E. FELDMAN, M. D.²

The necessary search for newer and perhaps more effective ataractics has resulted in an interest in the therapeutic potentialities of N-Methyl-Piperdyl-(3)-Methyl-Phenothiazine; also known as "Mepazine" or "Pacatal."¹ This drug, under the trade name of "Lacumin," has been tested upon the European continent by Werenberg(1), by Laborit and Huguenard(2) and Kleinsorge(3). In the United States and Canada, Rudy *et al.*(4), Bowes(5) and Kline and Jacob(6) have reported upon their experiences with this drug.

Animal pre-testing of Pacatal indicates that it has a relatively low acute-animal-toxicity and causes no hematological deviations from normal at any dosage level. Studies(7) indicate that the administration of dosages of 100 mg./kg. to dogs results in lymphocytic infiltration of the liver and active degeneration of spermatic cells.

The fate of Pacatal in the body is unclear. Hendriksen *et al.* (8), found that rats deposit Pacatal in various tissues and that a relatively small amount is eliminated. They, however, did not find evidence of cumulative effects.

Pharmacological studies(7) with Pacatal indicate inhibition and stabilization of the central and peripheral regulatory mechanism of the autonomic nervous system and direct depression of the central nervous system, manifested clinically by sedation (without hypnosis), and, potentiation of narcotics, hypnotics and analgesics.

METHOD

CLINICAL MATERIAL

This report summarizes the experiences of the Topeka State Hospital Medical Staff with 130 patients who received this drug. These patients were chronically psychotic and refractory to all previous forms of therapy. Of this patient-group, 12 have been excluded from all aspects of the evaluation

¹ Pacatal provided through the courtesy of Warner-Chilcott Laboratories.

TABLE 1

COMPOSITION OF TEST GROUP UPON THE BASIS OF DIAGNOSTIC CATEGORIES

	No. of Patients	Percent of total group
Schizophrenic reactions	86	72.9
Chronic brain syndromes.....	16	13.5
Psychoneurotic reactions	8	6.8
Manic-depressive reactions ...	4	3.4
Mental deficiency	4	3.4

other than those pertaining to toxic effects, because their medication had not been continued for at least 2 months. The remainder of the group received Pacatal for from 3 to 6 months. Table 1 summarizes the composition of this test group upon the basis of diagnostic categories. The severe chronicity-of-illness of the patients tested is reflected in the statistics of Table 2. It is pertinent to note that not a single patient tested had been mentally ill for *less* than 2 years, and, the great majority had been ill for more than 10 years.

CRITERIA

The method of evaluating response to Pacatal, with the criteria upon which this evaluation is based, is covered in detail in a previous report(9). It consists of the clinical rating of various aspects of behavior upon a 4-point scale, and the conversion of these individual ratings into an over-all rating (for total response to drug) using a 6-point scale.

ADMINISTRATION

Pacatal was provided in 25 mg. and 50 mg. tablets for oral administration, and, 2 cc. ampules (containing 25 mg./cc.) for intramuscular use. Actual dosages administered varied from 75 mg./day to 900 mg./day, with the majority of the patients receiving

TABLE 2

RELATIVE CHRONICITY-OF-ILLNESS OF TEST GROUP

Duration of illness (years)	Percent of total group
0-2	0
2-5	15.5
5-10	10.4
10 +	74.1

150-300 mg./day. Most of the patients were started with a dosage of 100 mg./day which was then gradually increased, depending upon patient response or the appearance of toxic symptoms. Table 3 indicates the relative proportion of patients on various dosage levels, each of the dosage levels having been found to be optimal for the patient concerned.

PRECAUTIONS

At the time this study was initiated, there was comparatively little literature available concerning the toxic effects of Pacatal. One report(10) stressed dryness of the mouth, blurring of vision, and, constipation. Kline (6) observed elevation of temperature, drowsiness and urinary retention, and, Bowes (11) encountered visual disturbances, anorexia, constipation and dizziness.

A standard type of precautionary regime for testing of an ataractic drug was instituted, with monthly examinations of blood and liver function, periodic but routine recording of blood pressure and the usual fractionation of dosages of analgesics, sedatives, etc. The known, reported side-effects were listed and the clinicians doing the actual testing were requested to note these and any other effects that appeared, and to correlate the appearance of a side-effect with the duration of medication and dosage. They were also requested to provide information as to the efficacy of any antidotes that were used symptomatically.

RESULTS

IMPROVEMENT

Table 4 indicates the effectiveness of Pacatal upon the various evaluative criteria of be-

havior. The criteria are listed in sequence of diminishing efficacy of drug.

Table 5 indicates the over-all effectiveness of Pacatal upon the various diagnostic categories.

SIDE-EFFECTS

Table 6 lists the side-effects encountered in the order of diminishing incidence. The fluctuating leucocyte counts observed by Bowes(5) and Werenberg(1) were not encountered in this series of patients.

DISCUSSION

At first glance, the results may not appear to be as good as those obtained with previously tested ataractics(12). A markedly improved rate of 11.9% in the schizophrenic group would hardly warrant Bowes' referral to Pacatal as a "promising new ataractic." However, when the severe chronicity of the schizophrenic patients tested is taken into consideration, the combined moderately and markedly improved rate of 42.9% does warrant some optimism as to the potentialities of this drug.

An additional asset of the drug, which was not measurable in the study, is the pleasant subjective feeling produced by Pacatal. It was described by some patients as "it makes me feel better," or "I feel less miserable," or "I feel out of this world" or "I feel less nervous." Some patients developed such a strong sense of well-being that they were reluctant to communicate their discomfort resulting from some of the side-effects for fear that the drug would be withdrawn. Many patients, despite blurred vision or excessive dryness of the mouth were eager to continue medication. Bowes(5) observed similar effects and reports a patient who had been changed from chlorpromazine to Pacatal saying, it was "like champagne after beer."

The drug appears to exert maximal therapeutic effects at dosages between 150-300 mg./day. Very few patients showed additional improvement (Table 3) when the dosage was increased above these limits, and the drug appears to be without effect in dosages of less than 75 mg. day. Hiob and Hipkins(14) found the most efficacious dosage level to be 300 mg./day though they frequently went as high as 600 mg./day.

Depression	1	0.8

The numbers of patients in the categories of Chronic Brain Syndromes, Psychoneurotic Reactions, Manic-depressive Reactions and Mental Deficiency were insufficient to

warrant any conclusions as to the therapeutic efficacy of Pacatal upon these syndromes.

As seen in Table 4, Pacatal follows a pattern similar to that of other ataractic drugs in its influence upon various aspects of behavior (12). Appetite, sleep, tension, combativeness, accessibility and hyperactivity show the best responses, whereas insight, affect, judgment, etc., respond disappointingly—as they do with other ataractics as well.

The most common side-effect noted was dizziness. This usually appeared shortly after medication was instituted and gradually subsided within two weeks. It was rarely incapacitating. The second most common side-effect was drowsiness which followed a self-limiting pattern similar to that observed with dizziness. The drowsiness in

some cases was severe, and a few patients were withdrawn from the study because of it. Drowsiness that did not subside spontaneously within two weeks responded well to moderate doses of cerebral stimulant (5-10 mg. of Dexedrine).

Blurring of vision was a distressing complication in 16 patients. It was severe and prevented these patients from reading or participating in handicraft therapy. Apter and Rinsley (13) found that the visual disturbance was due to a combination of paralysis of ocular accommodation and a drying of the corneal epithelium because of diminution of tear production. Complete symptomatic relief was obtained by the oral administration of neostigmine, in dosages well below those levels which might produce toxic symptoms—usually 7.5-15 mg. once, twice, or three times per day. Those patients who found it necessary or desirable to do close eye work or to read fine print were further benefited by the instillation of one drop of 0.1% Eserine in each eye, once per day.

Dryness of the mouth was reported in but 7 patients. This side-effect responded well to the regime instituted for blurred vision. Gastro-intestinal symptoms were nausea, vomiting, diarrhea or constipation. Slurring of speech was noted in 8 patients. All responded well to lowering of the daily dosage of Pacatal.

Hypotension was occasionally encountered, but was never of serious magnitude. The fall in blood pressure was gradual, not exceeding 30 mm. of mercury and no cases of orthostatic hypotension were noted. Two patients developed jaundice within 6 days of the time that Pacatal was started and their medication was promptly discontinued. These patients were receiving 25 mg. of Pacatal q.i.d. and the jaundice appeared to be the usual type of obstructive hepatitis seen during ataractic medication, differing only in that the period of jaundice persisted at maximum intensity for 6 weeks before the icterus began to subside. These two patients did not appear ill and were comfortable throughout the course of the hepatitis. They have both completely recovered and now display normal liver function.

One patient developed severe depressive symptoms culminating in a suicidal gesture on the 16th day of medication. She was re-

ceiving 75 mg. of Pacatal per day. Her daily dosage was increased to 150 mg./day and the depression subsided.

SUMMARY AND CONCLUSIONS

1. Pacatal is capable of eliciting therapeutic responses in chronically psychotic patients.

2. It is most efficacious for those aspects of behavior which are related to increased anxiety and least efficacious for judgment, insight, orientation, memory and affect.

3. The clinically significant side-effects are those related to the atropine-like action of Pacatal. Untreated eye complications, following prolonged administration of Pacatal, may lead to ulceration of the corneal epithelium.

4. It is recommended that any prolonged ocular disturbance as a result of Pacatal medication be treated with Neostigmine.

5. All the side-effects produced by Pacatal can be obliterated by symptomatic medication, lowering of daily dosage or discontinuation of the medication.

6. The results obtained with Pacatal are encouraging and warrant further investigation upon a prognostically better group of psychotic patients.

THE DEFECTIVE DELINQUENT¹

PETER W. BOWMAN, M. D.²

A discussion of the so-called "defective delinquent" should be opened with the statement that the symptom of mental retardation can be defined as an entity of considerable complexity which invades the intellect, the emotions, and physiology of the human personality. At the same time it is proper to acknowledge that our concept of the defective delinquent has yet to benefit from the new, comprehensive approach based on insights, programs, and concisely defined and commonly accepted medical, educational, psychological, and social procedures.

I cannot hope to offer a detailed study of what constitutes defective delinquency. I can elaborate on our obvious inadequacies and suggest that we replace emotionally charged administrative discussions of how to dispose of those labelled "defective delinquents" with a scientific analysis aiming at a definition of the problem as the only objective and acceptable basis for communication, legal provisions, treatment facilities, and a preventive program if possible.

As I have pointed out previously⁽¹⁾ we do not have a commonly acceptable definition of the term "delinquency." Often it is applied to misdemeanors and minor offenses committed by children or adolescents. Sometimes major crimes like robbery, manslaughter, first- and second-degree murder, have been termed "delinquency."

To the lawyer, delinquency has primarily legal implications. The teacher might refer to delinquency when he faces behavior disturbances which he cannot handle with the generally accepted and available disciplinary methods. To the psychiatrist the term "delinquent" is highly unsatisfactory since it suggests merely the violation of a social law without any reference to the motivation, circumstances, or medical and psychological diagnoses.

In the literature, we find that relatively little attention has been given the defective

delinquent. Some authors have studied the history of defective delinquency. Others have reported the legal problems involved, such as propriety of commitment or detention, draft of laws to dispose of defective delinquents in reformatories, penitentiaries, reform schools, or special prisons. Administrators have elaborated on the assumption that our state training schools are to be residential schools which cannot and will not tolerate behavior disorders, or, by implication, neuropsychiatric disorders⁽²⁾.

Many papers reflect an underlying anxiety about and intense rejection of the defective delinquent, primarily because of our obvious failure to integrate defective delinquency in either penology or psychiatry.

Sometimes the activities of the so-called "incurable mentally retarded" persons confront administrators and personnel of our generally understaffed and inadequately equipped state training schools and hospitals with problems of considerable proportions and consequences to the institutional operations, or to public school systems and other community agencies.

It is a known fact that courts have used a defective delinquent law or a juvenile defective delinquent act to handle defendants who were mentally retarded, on the following charges: Assault, felonious assault, theft of currency, larceny, wanton and lascivious behavior, theft, property damage, arson, common runaway, breaking and entering, larceny, theft of bicycle, false fire alarm, indecent exposure, exposure of naked body, theft of an automobile without the owner's consent, breaking and entering with intent to steal, lewd and lascivious behavior, injuring of a gravestone, throwing stones at a filling station, fornication, cruel treatment of animals, tampering with an automobile, throwing rocks large and capable of causing injuries, throwing a book at an individual, said book being large and capable of causing grievous injuries, for the best interests of the child and the protection of the community (patient's age 8½ years), manslaughter, rape, sodomy, infraction of institutional rules and regulations, etc.

¹ Presented at the North Eastern Regional Meeting, American Association on Mental Deficiency, October 1956, Southbury, Conn.

² Mental hospital administrator and superintendent, Pownal State School, Pownal, Me.

If commitment to an institution under these provisions is automatically for an indefinite period or for life, we must ask ourselves whether a delinquent, mentally retarded person is criminally responsible.

As Board (3) has pointed out, administration of a criminal law implies several value judgments:

1. Society is entitled to protection from further malfeasance by the criminal. A subsidiary value judgment is that a degree of punishment or isolation can be imposed on the criminal as a method of securing this protection.

2. Society is entitled to protection from potential criminals, from first offenders as well as repeaters. A subsidiary value judgment is that apprehended criminals can be punished by society to create deterrent examples before the law as a warning to potential criminals.

3. Society is best served by humane administration of the law consistent with the humane purpose of the law.

These value judgments he condenses into 3 aims in administering criminal law: 1. Preventing further malfeasance by the criminal; 2. deterring others from committing criminal acts; 3. humaneness towards criminals.

When we apply these 3 principles to the alleged defective delinquent we are immediately confronted with a number of questions.

What constitutes defective delinquency? Does it include a mentally retarded person who committed a criminal act or simply a misdemeanor, who displayed acting-out commonly seen in growing children? Does a mentally retarded person become a defective delinquent because of repeated infractions of institutional rules? Can an 8½ year-old mentally retarded boy be classified as a defective delinquent because of an alleged need to "protect him and the community" without even a charge, let alone a conviction? Is it possible to state that a mentally retarded child is considered a potential criminal though he has never committed a crime?

Who has the justifiable authority to pronounce the existence of defective delinquency? Is it to be an exasperated parent who for any number of reasons has failed to train and integrate his mentally retarded child in the family or in the community? Is it to be the prejudiced institutional superintendent who is forced to operate with an inadequate staff in excessively overcrowded

quarters which lack modern diagnostic treatment and educational facilities? Is it to be the public school principal who is forced to place mentally retarded children in grades far beyond their intellectual ability merely because of chronological age and physical growth?

A clarification of these and other questions will possibly lead to a consideration of the deterring values and the humaneness of marking mentally retarded persons as "defective delinquents."

Before presenting some previously reported case histories (1), I call attention to the fact that encephalitis, meningitis, the epilepsies, and other medical, psychiatric and metabolic organic disturbances can contribute to and occasionally cause violent and aggressive behavior.

Persons so afflicted, if intellectually competent, usually are placed in mental hospitals. If their intelligence falls within the range of mental retardation, functionally or potentially, I cannot see how we can escape our responsibility to accept them and to deal with them constructively in our institutions for the mentally retarded. They require psychiatric treatment and should be handled by psychiatrically trained nurses and attendants, not by correctional officers in a penal institution.

The following case histories are typical of patients who have been committed as defective delinquents (1):

1. This 13-year-old boy was committed to an institution for the mentally retarded in 1944 on a charge of property damage and assault. Patient was born at full term, acquired first teeth at 7 months, had whooping cough and measles at 6 months. He also had chickenpox and mumps at a later age. He began school at 7, attended a school for the deaf from September 1936 until 1944. While there he was considered unable to make satisfactory progress as he was "troublesome" and "irritable" with the other children. It was said that he attacked other children and required close supervision. It was suggested that he be promoted on a social basis and was finally employed in the laundry of the school because there was not enough help. However, at the end of the school year, 1944, while on vacation, he was charged and committed as above stated.

We know very little of the father and mother except that they were divorced a year prior to patient's commitment to the institution for the mentally retarded.

His subsequent institutional history indicates that the professional staff felt that his retardation was

due to a lack of hearing and the resulting speech difficulties. It is felt that the boy has considerable undeveloped resources and could progress further, not in grade work, at least in vocational work. Evidently, he had not had much opportunity for vocational guidance and training. Subsequently this boy regressed in his ability to write because of lack of individual attention and educational opportunities at the institution and he was placed in the manual training shop where he became expert in chair-caning, sewing brooms, etc. He displayed an active interest in ballgames, pitching horseshoes, and other recreational activities.

2. This 16½-year-old boy was committed to an institution for the mentally retarded on a charge of sexual assault on a minor male. He was the third child in order of birth, started to walk at 18 months and was reported normal in all other matters. He entered school at 6, and was attending the eighth grade when sent to the institution for the retarded. He was first committed to the state school for delinquent boys in 1952 and was released on parole in 1953. He was picked up by the police on complaint that he had taken indecent liberties with a 4-year-old boy. It was later learned from his mother that he had tried to perform sexual acts with a younger brother. Father is said to be a member of a family of 9 children; he cannot read or write but can sign his name. He is the proprietor of a beer parlor and has also done some work with construction companies, before he opened his shop. He has been known to indulge heavily in alcoholic beverages. In 1938 his wife secured a divorce.

Patient's mother is said to have been always the frail woman of the family. She has been subject to asthmatic attacks since age 14 at the time of the menarche. She is said to have had good marks in school and at one time was taking a correspondence course to finish high school. She always hated alcohol, but she did take it for her asthmatic attacks, chiefly brandy "prescribed by her doctor." In 1950 she took various kinds of medication and brandy and one night attempted to kill the patient by hitting him over the head with a hammer, soaking the bed linen in oil and setting it on fire. The patient, however, escaped. Mother was subsequently committed to a state hospital for observation.

Patient did not stay at the institution for more than 3 weeks because psychiatric and psychological evaluations indicated borderline to normal intelligence. He was discharged in the custody of the state school for delinquent boys.

3. This 12-year-old girl was committed to an institution for the mentally retarded in 1949 on a charge of larceny. Patient was the fourth child in order of birth; she is said to have walked and talked at 4. For some years she had been boarded in various foster homes by her father and was known to have had sexual relations with both boys and men prior to commitment to the institution. She was expelled from school because of truancy and as a behavior problem, after she had been promoted to the third grade, although her I.Q. rat-

ing was approximately 46. A few months prior to commitment, father was arrested on a charge of incestuous relations with the patient. Mother deserted father and children several years before. No other information given.

Subsequent institutional history shows that the patient became increasingly disturbed, developed delusions of persecution, visual and auditory hallucinations, and was finally transferred as psychotic to the state hospital at age 17.

4. This 16-year-old boy was committed sometime in 1945 on charges of felonious assault on his father, who might be his step-father since there is a question as to paternity.

Early medical history is uneventful.

Mother is of questionable conduct; described as mentally retarded; left her family when patient was of preschool age, after she had rejected and mistreated her children for a number of years. Father also considered mentally retarded, a seaman by trade, now deceased.

Two grandparents, several aunts, uncles, and first cousins have been convicted or sent to state institutions. Two uncles and 4 cousins have been sentenced to from 24 to 48 years in state prisons on the following charges: manslaughter, robbery, breaking, entering and larceny, indecent liberties. Eight cousins and 2 aunts and 1 sister have spent an undetermined number of years at the state school for delinquent girls. Three cousins and 2 uncles have been committed for an undetermined period to a state school for delinquent boys. One aunt was committed to a state hospital, 1 cousin to a reformatory for men, and 1 sister and 2 aunts to a reformatory for women.

We know, therefore, that the patient was raised in an atmosphere of maternal rejection, neglect, and possible abuse, of paternal ignorance and questionable paternity. To this, we can add a remarkable family record of criminality. With this background in mind, it is not surprising to read patient's institutional record:

A psychometric test at time of admission to the institution for the mentally retarded indicated a mental age of 7 years, and an I.Q. of 47. He was assigned to manual training classes but was uncooperative and refused to carry out instructions. Beginning in January of 1946, he accomplished his first escape and such attempts continued throughout his stay at the institution. In 1947 he broke into a camp with another patient, stealing clothing, rifle, shells, flashlight, etc. Subsequently he fired a shot at the game warden who attempted to apprehend him, but he was finally subdued. In accomplishing his several escapes, he did considerable damage to institutional and private property, and to his own clothing. In November of 1949 one of his escapes resulted in his apprehension in New York City. He was taken to Bellevue Hospital and eventually returned to the institution. From time to time sharpened knives, files, etc. were found on his person. He became more and more uncooperative and belligerent. On 3 occasions he had what was described as "epileptiform seizures." In February 1953 he, with 3 other patients, es-

caped, set fire to the dairy barn of the institution. They were apprehended and placed in the county jail to await grand jury action, when they were sentenced to the reformatory. At the reformatory it was reported that patient's health was good with the exception of what appeared to be attacks of epilepsy, for which he was at times hospitalized. He was tried in first-grade work, but allegedly could not absorb the data and was excused from attending. After serving his minimum sentence at the reformatory his case was taken up by the parole board and it was decided he should be taken to the Probate Court for re-commitment to an institution for the mentally retarded. Three weeks after his re-commitment he had recurring epileptic seizures for which medication was administered. He gradually acquired a persecution complex, threatened to kill attendants with a knife, developed delusions that medication given him made him crazy, threatened suicide and was obsessed with never being able to be released from the institution for the mentally retarded. Two of his fellow escapees had been paroled from the reformatory, probably because of a higher mental age. Sometime in 1954 patient developed symptoms resembling a prison psychosis and he was transferred to a state hospital.

I cannot agree with Lurie, Levy, and Rosenthal that "the defective delinquent's prognosis with regard to cure of his behavior difficulty is uniformly poor" and that "at present commitment for life to a custodial institution especially equipped to treat this type of child offers the only solution(4)".

I rather admit that there prevails an appalling lack of knowledge of what constitutes "defective delinquency" if such an entity exists at all,⁸ that generally the professional approach has been negative and remiss.

It might be of academic interest to investigate the reasons for this situation. I propose, however, that we be practical and search for constructive answers.

Already in 1951, Benda, Farrell, and Chipman(5) recommended that we "abandon as much as possible all generalizing categories and proceed to an investigation of these specific conditions with which we are dealing. Only in this way can each condition be understood and treated according to its specific need." This program should be used in our approach.

In a report of the Citizens' Committee for Children of New York, Inc.(6), it is stated that there is "no formal recognized coordination between or among Federal, state, and

local public agencies, or between public and voluntary programs in the field of mental retardation; that there is no clear allocation of public responsibility in the local community for early case finding, comprehensive diagnosis, or parent counselling; that there is today no organized program for public and professional education about mental retardation and about the needs of persons found to be mentally retarded."

I should like to add that mental retardation in its implications and consequences and with it the symptom of what we now call "defective delinquency" cannot be separated from our general social concern, expressed in public health, mental health, welfare, educational, correctional, and spiritual activities. Yet segregation is the basic idea which has excluded the mentally retarded from educational and social community activities and advancements, which has sent thousands of patients to state institutions for a predominantly custodial life of deprivation and confinement.

Because of a remarkable degree of professional resistance and ignorance, starting at our graduate schools of education, social work, psychology, and even in our foremost medical schools, the symptom of mental retardation has yet to emerge as a generally accepted matter of scientific concern and professional status(7).

At the institutional level we observe a pathetic lack of facilities and staff which is matched by remarkably overcrowded dormitories and long waiting lists. In this atmosphere behavior disorders are events which disturb the functions of the institution, disrupt the staff, and contribute materially to low morale among patients, staff, and patients(1, 2, 3).

These facts present an extraordinary challenge: Our thinking on the symptom of mental retardation is in a stage of transition. Establishment of special classes and provisions for refined educational techniques and services at the community level coincide with the trend to social integration of the retarded in the family and in community sheltered workshops.

This process demands that we give serious thought to investigating the changing functions of our institutions for the mentally retarded.

⁸ The Diagnostic Manual of the American Psychiatric Association does not list "defective delinquency" as a diagnostic entity.

There is an obvious trend to send to our institutions children who present psychiatric disorders which cannot be taken care of in the community, or who are so severely retarded that they require protection and a form of training which the community does not provide(9). This means that our institutional programs will require revision, that our staffs will have to adjust to more problems, to search for new answers and therefore to consider scientific research as an essential and necessary part of every institutional operation(8). Our treatment programs will have to be based:

1. On the well-established recognition that we are engaged in a multidisciplinary activity. The mentally retarded patient presents complicated and challenging diagnostic and treatment problems in the fields of medicine, clinical psychology, special education and social work. The so-called ancillary services, occupational, recreational, physio- and hydrotherapies, music therapy, speech therapy, nursing care, etc., have become an integral part of treatment.

2. On modern diagnostic processes: detailed history of the presenting symptoms including pertinent medical data of the prenatal, paranatal, and postnatal development, psychological evaluation, detailed social history to permit a thorough understanding of the patient's environment, clinical examination to include evaluation of vision, hearing, speech, motor coordination, of serological, hematological and chemical tests, of a psychiatric evaluation wherever it applies, integration and coordination of all findings in the diagnostic staff conference where etiological factors will be identified, where a working or final diagnosis is arrived at and where prognosis and a comprehensive treatment program are being formulated.

3. On sufficient understanding and co-operation between the various services to effect, as much as humanly possible, staff accord in carrying out treatment for the individual patient.

This approach places a heavy responsibility on the administrative officer and the various department heads who have to plan and present an operating budget to provide the services and facilities necessary. They must use all proper means of public education, public relations, and communications, to gain

the institutional objectives by convincing citizens and their legislative representatives of the need for the requested funds.

Recruitment of professional and non-professional staff often will require reconsideration of job classifications at the local as well as at the state level, establishment of competitive salary schedules and of scholarships for graduate studies if we are to find the people to do the job.

Our building program must include provisions for treatment and dormitory facilities for disturbed patients. Functional architectural design to create a proper atmosphere must gradually replace the overcrowded mass quarters of the custodial care era, when it was important to detain as many "inmates" and as cheaply as possible. We will have to plan to locate any new institution which might be planned for the mentally retarded close to existing medical centers to overcome our professional isolation and to benefit from, as well as contribute to, existing clinical, academic, and research programs.

There is an increasing awareness of these changes. However, we have still a long way to go until we can practice what we have recognized to be necessary for successfully dealing with mental retardation. Until this time I am inclined to replace the term "defective delinquency" with "social delinquency."

IS THE HUMAN PERSONALITY MORE PLASTIC IN INFANCY AND CHILDHOOD? ¹

IAN STEVENSON, M.D.²

"The doctrines which best repay critical examination are those which for the longest period have remained unquestioned."

A. N. WHITEHEAD

No assumption of modern psychiatry enjoys greater acceptance than the belief that human personality is more plastic in infancy and childhood than in later years. Although widespread today, the belief belongs to modern times. The writings and practices of ancient Greece and Rome showed great concern for the education and training of children; and no less for those of adults. We cannot say exactly when the modern emphasis on childhood training and relative neglect of adult training began. In the 16th century St. Ignatius made a clear statement of it. He declared that if he could have the teaching of a child until the age of 6, he did not care who instructed him afterwards. He firmly believed that nothing could undo the teachings of the early years. From about this time on, a belief in the paramount importance of childhood experience in the formation of personality forms a central doctrine of many systems of psychology (1, 2).

A balanced view of the contributions of heredity and environment to human personality slowly emerges in our literature (3, 4). Extreme positions in this old controversy no longer appeal, and none will be adopted in this paper, for the question at issue is not whether environment or heredity contributes more to the formation of human personality, but whether the contribution of environment occurs unevenly. The environment plays upon the organism from the moment sperm and ovum unite until the end of life. *A priori*, we have no grounds for believing that the environment exerts greater force at one period than at any other. Some proponents of this belief have said that the helplessness and

necessary dependency of the infant upon his parents account for his susceptibility to their influence, but this is to offer an explanation of an assumption rather than a foundation for it. Helplessness and dependency do not necessarily render the personality more malleable if we may judge by the behavior of the sick and the aged.

Diverse observations made over the past 10 or 15 years throw doubt on the assumption of an uneven distribution of environmental effects. Taken together they provide a rather formidable obstacle to its acceptance. They do not disprove the assumption, but they threaten seriously the claim that it is already proven. I shall consider the data which have brought me to this conclusion under 4 arbitrary headings, any one of which may include material relevant to another aspect of the problem.

REVIEW OF RELEVANT DATA

CHILD TRAINING PRACTICES AND THE LATER FORM OF THE PERSONALITY.

The literature of psychiatry abounds in articles asserting causal connections between the early experiences of life (especially training practices) and the later personality. The far fewer articles reporting objective studies of such relationships fail to support the assertions made (5, 6, 7, 8, 9). Thurston and Mussen (5) contribute a review of earlier studies in addition to their own negative empirical study. Orlansky (8) and Lindsmith and Strauss (9) have reviewed the empirical studies and concluded that the published data fail to demonstrate a consistent relationship between child training practices and adult personalities.

Studies of the relationships between child rearing practices and adult personality frequently fail to define clearly the traits under scrutiny. A notable exception is the research of F. Goldman-Eisler (14) into the connection between breast feeding and the later exhibition of traits of "orality." Goldman-

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² Address: Dept. of Psychiatry and Neurology, School of Medicine, University of Virginia, Charlottesville, Va.

Eisler subjected the data derived from careful studies of her adult subjects to a factorial analysis from which emerged a definite correlation between the kind of breast feeding experienced (*i.e.*, early weaning or late weaning) and the later occurrence of certain personality traits (characterized respectively as orally ungratified and orally gratified types). The fact of a correlation is thus clear, but it is open to two interpretations. The later personality may arise from the impact of the earlier experiences, but Eysenck(15) has pointed out that genetic factors may also account for the correlation in the following way. The polar oral types (gratified and ungratified) correspond rather closely to the extravert-introvert dichotomy familiar in Jungian psychology. We may plausibly suppose that introverted mothers tend to have introverted offspring through genetic factors alone, and that introverted mothers also tend to wean their infants earlier than do extraverted mothers. Thus the established correlation may arise from either genetic or experiential factors. The question of which explanation is the correct one must await further research.

It may be objected that parents influence their children through their attitudes to the children and that the actual training practices they adopt are of quite secondary importance. This shifts the argument to another area, but one in which there are even fewer objectively derived data. Nothing is gained by inferring attitudes on the part of the parent from the specific child training practices for, as mentioned above, no causal connections have been demonstrated between the training practices and the later personality. Moreover, no correlations have been demonstrated between child training practices and the attitudes of parents towards children. Some authors have claimed, for example, that early bowel training implies compulsive rigidity on the part of the mother or that late weaning reveals indulgence and affection. Yet the same training practices occur in widely different cultures in which the parents seem to take up quite different attitudes towards the children. One particular training practice, *e.g.*, restraint of infants, may occur in many different cultures, but in each of these cultures occur other child training

practices which differ(8). The occurrence of one or even several particular child training practices permits no valid inference either about other training practices in the same family or culture, or about the over-all attitude of the parents to the children(10). The statements of patients concerning the attitudes of their parents towards them as children obviously deserve no credence when we are studying the origins of the personalities of the patients. In the first place, these personalities may have provoked the alleged parental attitudes, and secondly, patients can wildly distort the attitudes of their parents in reporting them.

When it becomes possible to observe, rather than merely assume the attitude of parents towards children, an important connection between these attitudes and the behavior of children can sometimes be demonstrated. Johnson and Szurek studied a number of children and their parents in therapy. In this way they related the attitudes and suggestions of the parents to the children and the behavior of the children. Parental attitudes and impulses, often unconscious and communicated covertly, promoted a wide variety of psychophysiologic and sociopathic symptoms in these children(11, 12, 13). Nothing could demonstrate better the influence of one human on another. But the questions of interest to us here are whether parents exert a permanent influence on children and whether they exert a greater influence on children than upon each other. These questions the studies of Johnson and Szurek cannot, and were not intended to answer.

CHILD TRAINING PRACTICES AND THE OCCURRENCE AND FORM OF LATER MENTAL ILLNESS

If the experiences of childhood importantly influence the later personality, we should expect to find some correlation between such experiences and the later occurrence of mental disorders. In fact, no such correlations have ever been shown.

Moloney reported an exceedingly low incidence of mental illness among the Okinawans(21). He concluded that the child rearing practices of the Okinawans (which include a great deal of oral gratification and

affection) fortify them against the occurrence of mental illness; yet Moloney's figures of admissions to hospitals for mental illness provide no reliable estimate of the real incidence of mental disease in Okinawa. At the time of Moloney's observations, the admissions to hospitals for psychiatric disorders must have reflected quite inadequately the incidence of mental illness among these people. Moloney himself comments on 3 factors which alone would throw doubt upon the usefulness of the figures he quotes. There were almost no psychiatric facilities on the islands; the natives kept the mentally ill at home; and they treated the mentally ill with derision and more serious forms of cruelty, including physical violence. (Parenthetically, this last feature of their behavior might make one doubt the purported absence of mental illness which in Moloney's paper was apparently defined as psychosis.) These factors would all tend to reduce the admissions to hospitals, but not the occurrence of mental illness.

But apart from the questionable validity of Moloney's figures, a study of Okinawans in Hawaii (where the Okinawans continue the same child rearing practices) showed that this racial group has a considerably higher incidence of mental illness than other racial groups in Hawaii (17). Thus even if we grant that Okinawans adjust well to the circumstances of their own islands, they apparently adjust less well than other groups to certain changed circumstances and have no special immunity to mental disorder.

If good mothering does not confer protection against mental disorders, it may be that bad mothering or lack of mothering promotes mental disorder. On this subject there are more data, although none that can permit generalizations. Anna Freud studied a group of children who had been unusually deprived, through the exigencies of war, of all that is generally considered necessary in the way of good mothering care (23). Yet these children made remarkably good adjustments, perhaps since they were in a group obtaining from each other what they did not get from a mother. This subject will be taken up again later.

It is frequently alleged that parental attitudes contribute to the formation of a per-

sonality specially susceptible to schizophrenic reactions. Yet different studies on the parents of schizophrenic patients fail to show consistent portraits of the personalities of the parents or to confirm the popular stereotype that the mothers are excessively anxious, domineering and solicitous with regard to the child who later becomes schizophrenic (16, 17, 18, 19). Moreover, the parents of a child who later becomes schizophrenic more often than not have raised other children who developed normally. No doubt studies of environmental influences on the formation of personalities predisposed to psychoses labor under severe handicaps. This should make us more rather than less cautious in attributing psychoses to such influences. We should be all the more cautious in view of the much clearer evidence of important genetic factors underlying psychoses (20).

That the forms of mental illness vary widely in different parts of the world is abundantly clear from comparative studies (24, 25, 26, 27). Some of these differences arise from disagreements between different cultures as to what constitutes a mental illness. Forms of behavior which are considered psychotic in our culture may find acceptance and even approval in another. However, apparently similar mental disorders, *e.g.*, schizophrenia, do show somewhat different forms in different cultures (25, 27). Psychotic patients in India (25) and in Japan (26) apparently exhibit much less violent behavior than is customarily seen in the mental hospitals in the West, but we have no data which might permit us to attribute such differences exclusively to training in infancy. For in India passivity, and in Japan obedience and obligation, form a central part of the training not of infants only, but of every one of any age.

THE EFFECTS OF ISOLATION IN CHILDREN AND ADULTS

That the isolation of children from other human beings can exert a markedly destructive effect on personality has been known for centuries (28). Recently a number of studies have tried to sharpen our understanding of the effects on infants and children of isolation and the concomitant deprivation (29, 30).

31, 32). The work of Spitz has drawn widespread attention and been generally interpreted to confirm the importance of adequate mothering during infancy and childhood. Spitz compared 2 groups of infants who were apparently raised in similar physical circumstances. One group received abundant mothering, while mothering attentions were sharply curtailed in the other group. The second group compared to the first, showed an increased morbidity and mortality and a failure to develop. Pinneau has criticized Spitz's work on the grounds that he failed to allow adequately for a number of factors which could have accounted for the differences between the 2 groups, *e.g.*, genetic differences, and different exposures to diseases such as measles which carried off many of those who died in the deprived group(33). But even if we grant that Spitz's data support his conclusion concerning the harmful effects of isolation on infants, two further questions remain. Are such effects any less in adults? What is the duration of such effects on infants? I shall take up the first question next and return to the second later.

In general human beings are rarely as cruel to adults as they often are to children. It is difficult to find an adult situation which resembles exactly the predicament of institutionalized infants. One approximately comparable situation may occur during the artificial reduction of sensory stimuli as in the experiments of Heron(34, 35) and Lillie(36). The subjects of these experiments were isolated almost completely from sensory stimuli. Institutionalized infants are usually isolated from close human (so-called affective) contact rather than from all sensory stimuli. However, in the "Foundling Home" studied by Spitz(30) the babies received a greatly reduced sensory stimulation due to screening sheets around the cots and high walls between the cubicles. Such features make the situation of these infants resemble rather closely that of the adult experimental subjects under discussion, although there are also differences.

In the experiments with adults, the subjects experienced tension and anxiety which were followed in those who could stand the

experience long enough by marked disorders of perception and thinking. Hallucinations and delusions occurred in some of the subjects. Few subjects could tolerate these experiences for more than a day or two at most. For this reason the possible effects of prolonged sensory isolation could not be estimated from such experiments.

Another adult situation with some resemblance to that of institutionalized infants occurred in concentration camps(37, 38, 39, 40) and in some camps for prisoners of war(41, 42). In these camps the prisoners were not isolated from other people or from stimuli. However, the people with whom they were in contact were unable to provide them with anything like the usual amounts of psychological support because they were either hostile guards or fellow-prisoners who were in the same desperate plight themselves. It cannot be said that loss of affection was the only stress to which the prisoners were exposed. Most suffered from malnutrition and many were subjected to physical maltreatment. However, it seems reasonable to conclude that the main stresses were psychological from the following facts: first, marked responses occurred almost immediately and before the effects of starvation could have influenced behavior; secondly, the psychological responses were greater than those accompanying starvation alone(43, 44); and thirdly, the responses to the situation were far from uniform among those who were receiving the same diet and mistreatment. Different responses could be correlated with different attitudes and personalities(38, 42). Parenthetically, children adapted to concentration camps much more readily than adults and the aged least of all(37).

Turning to the observed responses of inmates of concentration camps and prisoners of war camps, we find an extraordinarily high incidence of psychological disturbances. Severe apathy occurred almost universally; almost as common was the exhibition of fiercely self-interested and hostile behavior. For many prisoners the psychological effects were even more devastating and extended to stuporous states, dissociated states and death. Some of the inmates deliberately committed suicide by annoying the guards to the point

where the guards shot them or by running against the electrified wires around the camp. Many prisoners died without sufficient apparent physical cause and hence presumably from the psychological effects of their situation. It is naturally impossible to estimate the incidence of psychoses, suicides, and other deaths from psychological reasons in these camps, nor is it possible to estimate the total duration of the effects, although for many persons the effects are known to have lasted for many years.

As I said earlier, the experiments of sensory isolation and the stresses of concentration camps certainly do not exactly resemble the situation of institutionalized infants. Nevertheless the situations have enough resemblance to permit a comparison in which adults appear no stronger than infants. The point of making such a comparison is not to suggest that infants cannot be damaged by isolation, but to remind ourselves that adults are no less vulnerable. The response of infants to isolation is not an infantile one, but a human one. Studies of the effects of isolation on infants teach us the importance of affection to all humans; they cannot prove its greater necessity for children than for adults.

IMPERMANENCE OF PSYCHOLOGICAL SYMPTOMS OF CHILDHOOD

Many studies on institutionalized infants and on children with psychological disorders have not included lengthy follow-ups to observe their later course in life. In the studies of institutionalized infants by Spitz (30, 31, 32) and Bender (45) the children were followed only to early childhood. Gorfelfarb (46, 47, 48) followed a similar group of infants into early adolescence. In all these observations although the children showed variations in development, in general their maturation and adjustments fell far behind those of children raised under normal circumstances.

However, Beres and Obers (49) followed into late adolescence and early adulthood a group of infants who had been reared in institutions comparable to those of the other

studies cited. Of this group approximately half were judged to have made a satisfactory social adjustment. This seems like a remarkable degree of improvement, especially in view of the fact that such children are poorly endowed genetically, having usually unmarried or mentally ill mothers.

Caplan studied the children raised in the communal agricultural settlements of Israel (50). The rearing of these children is largely in the hands of professional workers who care for groups of children. The children live in nurseries and later in schoolhouses with other children of the same age. They spend some time with their biological parents, but nearly all the training and discipline are in the hands of the professional workers. Any one child will experience two changes of workers between birth and 3 years of age. The children become strongly attached to the members of their own group who apparently signify as much for them as do the members of their biological families. They usually remain with the same group until adolescence. The important observations of these children are that in their early years they show marked signs of psychological disturbance, *e.g.*, temper tantrums, thumb-sucking, and enuresis, but that in adulthood they are remarkably healthy both physically and mentally.

A somewhat similar transformation was observed in a group of 54 severely shy, anxious and withdrawn American children, who were disturbed enough to be examined in a child guidance clinic (51). At the time of the original evaluation, the children had a median age of about 7 years. They were then studied again 16 to 27 years after the initial evaluation. Two-thirds were found to be making a satisfactory adjustment and one-third a marginal adjustment. Those in the latter group were distinguished from the former by not fulfilling all their potential or deriving as much enjoyment from life as seemed possible. Nearly all of these children had married when they reached adulthood; many had married outgoing wives with whom they shared an active social life. Of the entire group only 2 were considered ill and only 1 of these was schizophrenic.

DISCUSSION

The data reviewed above throw doubt upon the belief that the events of infancy and childhood are necessarily more formative of personality than those of later years. None of the data reviewed conflicts with the established fact of human influence on human beings, or with our knowledge that the impact of one stress with a resultant strain modifies the response to a succeeding stress. What comes first influences the response to what comes after. The events of infancy and childhood will always have much importance because of their temporal precedence, but perhaps not because of any special fragility of the personality in those years.

This raises the question of the duration of the effects of a particular experience. As already mentioned, the assertion that the events of infancy and childhood always exert a special influence in forming the adult personality is still a statement of opinion, not of fact. Nevertheless, there are many reactions of adulthood which seem to repeat or imitate those of infancy and childhood. We may account for such resemblances in a number of ways without recourse to the hypothesis of a special impressionability of the personality in infancy and childhood.

ORIGINS OF RESEMBLANCES BETWEEN BEHAVIOR IN CHILDHOOD AND ADULTHOOD

The first possibility in accounting for such resemblances is that a conditioned response fails to extinguish because of some innate characteristic within the subject. Experiments in conditioning show that extinction of a learned response ordinarily occurs rather steadily in the absence of further reinforcement. The learned response is greatest immediately after the conditioning experiences and lessens progressively. However, we know that fears and other learned responses often fail to extinguish and, on the contrary continue an active and irrational course for many years. But we also know that the same events which stimulate such unextinguishing fears in some persons fail to do so in others. They may even have the opposite effect. An event which proves traumatic to one person may strengthen another.

The difference presumably lies in the way the event is experienced; that is, in the response the person makes to the stimuli which events bring him. But we have no reason to believe that infants are more liable to experience events in a fearful way than are adults. The capacity to acquire a fixed, irrational fear or other learned response is found in adulthood as much as in childhood, and perhaps more so.

Years ago, Breuer and Freud(52) remarked that "the hysteric suffers mostly from reminiscences." This is true, but it does not follow and has never been shown that the events of which the reminiscences are partial and distorted memories differ significantly for such patients, (or other patients with psychological disorders), from those experienced by other persons. As already suggested, the events of childhood may be experienced differently by the psychoneurotic patients. Or alternatively, the patients' childhood experiences are not unusual, but the patients later attribute a painful quality to them when viewed retrospectively from the current discomforts of adulthood, and mixtures of these processes may occur, because when a person has difficulty in mastering a current conflict, he can readily find comfort in attributing his difficulty to previous supposedly damaging events.

Resemblances between infantile or childish and adult responses may occur also when a series of reinforcements has followed the first harmful experiences of childhood. One harmful stimulus may succeed another so closely that the infant or child cannot recover his balance in time to react favorably to any event. This is perhaps an important factor in the devastating effects of institutions on infants and of prison camps on adults. The stress is unrelenting and harmful effects sustained. We have then not a personality "fixed" by early harmful events, but one bombarded by a continuous succession of harmful events. However, in ordinary life this situation must be rather exceptional. Few children meet unrelenting cruelty or neglect. Suffering children rather readily evoke a tender response in those around them. Most children encounter opportunities to unlearn whatever negative responses they

may previously have learned. If they fail to do so we can as plausibly attribute the difficulty to an innate defect of responsivity as to the severity of the previous stresses.

The most harmful of all experiences seems to be a deprivation of stimuli. Apparently growth cannot occur in the absence of stimuli from the environment. Institutionalized and isolated infants lack this stimulus and so fail to develop the qualities necessary for growth promoting contacts at the next stage of development. They thus fall behind their more stimulated contemporaries. But like those children who receive harmful stimuli, many of these isolated children do respond later to stimuli when they receive them. As mentioned in the preceding review of data, many of them eventually "catch up" with other more fortunate children of the same age (49). Since some institutionalized children can respond favorably to stimulation after infancy, the different responses to later experiences may lie in constitutional qualities rather than in the severity of deprivation.

Resemblances between childish and adult responses may occur when both express the unchanged character of the personality without having any causal connection. Infants at birth show wide variations in their spontaneous behavior and in their responses to stimuli (53, 54, 55, 56, 57). They exhibit the *anlage* of their fully developed characters. For example, Gesell (58) demonstrated in young infants the first expressions of fundamental traits of personality, *e.g.*, motor activity, affection, humor, curiosity, tolerance for frustration, etc. The infants studied showed these traits before the impact of parental behavior could have had anything to do with their origin. At 5 years of age the children exhibited the same traits, although in a more developed form, with remarkable consistency. It seems reasonable to suppose then that many of the responses of infancy and childhood may be not the causes of character, but their expression. To say this is not to deny that character can be changed through experiences, but as mentioned earlier, it is changed by the way in which events are experienced rather than by the events themselves.

Still another resemblance between infan-

tile and childish responses may occur in the process of regression, in which the adult returns to a previous pattern of behavior. But regression indicates a current stress too great for mastery. Like sleep, it is something of which we all are capable. The fact of returning to childlike behavior does not mean that the events of childhood were especially severe, or even especially important for the personality who regresses, although they may have been.

There exist then a number of ways in which adult responses to stress may come to resemble infantile or childish ones. In each of these ways we can account for the resemblance without the hypothesis of a special impressionability of the infantile personality which would make the events of the early years necessarily more important to the growth of the personality than those of later years.

SIGNIFICANT DIFFERENCES BETWEEN THE PERSONALITIES OF CHILDREN AND ADULTS

The problem may receive some further clarification from considering the important differences between the personalities and behavior of infants (and children) and adults.

We know that infants lack coordination and skill in the use of their musculature. We may assume, although we cannot positively know, that infants also lack the organization of perceptions and thoughts which comes in later life; yet we cannot deduce from these facts and assumptions a greater sensitivity to environmental influence. If we were to accept a comparison of the infantile mentality with that of the dreamer or the delirious patient, we would expect the infant to be less susceptible to outside influences than he is when his mind is more fully developed.

Impressionability in infants and children may arise from another important difference between them and adults. Infants and children lack past experience (memory) with which to evaluate current events, but this means that events have a different significance for the infant and child than for the adult. The infant and child respond to events according to their meaning for them. We have no grounds for believing that events are necessarily more meaningful or more irre-

quently given harmful meanings in infancy than in adulthood. They simply have different meanings. If you take a toy away from a child, he will probably cry, but if you tell him the mortgage has been foreclosed he will probably go on playing with the toy. We have no proof that within the world as he sees it, a stress is any harder to bear in infancy than in adulthood.

The experiential deficiencies of children do, however, place them at a special disadvantage in relationships with adults. Their fund of information is largely drawn from the supplies of parents. Children are like the country bumpkin in the hands of the city slicker. They are the perpetual captive audience of their parents. Their ignorance makes them more suggestible than adults. However, tests of suggestibility show that this reaches a peak in the years from 7-9 and thereafter falls off, being lower for obvious reasons in infancy and also in adulthood (58). In view of the marked influence of suggestion on personality, we may eventually have to ascribe special importance in the formation of personality to the years 7-9 as much as to the years of infancy and early childhood.

The physical helplessness of children which ties them for many years to one family greatly reduces the opportunities for the correction of faulty information provided by the parents. The ordinary adult has many more opportunities for increasing his experiences than the child who must largely live in a world of experiences chosen for him. The immobility of the infant makes him particularly dependent upon adults for stimuli with which to grow. (The prisoner in a concentration camp has the same inability to modify his experiences). Thus it happens that a great many persons reach adulthood with large areas of living completely unexplored. Some of the impression that personality becomes fixed in childhood may arise from the widespread constriction of experiences in many children and adults. Their personalities fail to change, not because they have permanently jelled, but because they never have the new experiences which seem essential for any change. Parenthetically, psychotherapy provides one kind of intense contact which can modify and undo the effects of the experiences of childhood. Psy-

chotherapeutic transformations of personality in adulthood should additionally warn us against viewing the adult personality as rigidly fixed in childhood.

Infants and small children exhibit a further difference from adults which at first glance may seem to make them more sensitive to environmental stimuli. Their emotions are less organized, less inhibited, and less suited to the occasion than those of most adults. Excessive or inappropriate emotional expression perhaps more than any other quality gives rise to the epithet "childish" when seen in adults. Yet from the fact that children's emotions lack the refinements of direction and discharge found in most adults, we cannot argue that children are thereby experiencing more durable effects from the events to which they respond. Such durable harmful effects seem to come much more often from the inhibition of emotional expression than from the reverse. Indeed, there may be a connection between the ability of children to express emotions freely and their well-known resilience to frustration. Very commonly a punished child becomes ready to forgive an angry parent long before the parent has recovered from his own anger (or guilt). Such resilience in turn probably accounts for the rarity in childhood of the prolonged hatreds and guilts which burden so many adults. As mentioned earlier, children adapted best of all to the horrors of concentration camps, and they can adapt in ways astonishing to adults to a wide variety of new situations. Such adaptability is not consistent with the view that children are more liable to show lasting effects of stresses than adults. What we know of the emotional life of children suggests that they may indeed be more impressionable than adults, but also more expressive of responses and less retentive of harmful effects. In short, their minds may be wax to receive, but not marble to retain the imprint of events.

This review permits no conclusions on this topic, except of the need for research. Such research may ultimately confirm in a scientific manner the belief that human personality is more plastic in infancy and childhood than in adulthood. Alternatively, it may show this assumption to have been a scientific myth. A

third and more probable result may be the demonstration that the human personality is more plastic during the early years in certain modalities and less plastic in others, and similarly we may find that adults can change more readily than children in some areas and less so in others.

SUMMARY

The article reviews data, much of rather recent origin, bearing on the assumption that human personality is more plastic in infancy and childhood than in adulthood. The available data permit the following conclusions:

1. We have no compelling evidence of a predictable relationship between child training practices and later personality.

2. Severe psychological stresses can have as marked effects in adulthood as in infancy and childhood, sometimes having greater effects in adulthood than in childhood.

3. Important personality changes occur after childhood (in the absence of treatment) including the disappearance of marked psychological disorders.

4. Infants reared according to ostensibly ideal methods of infant care show no greater immunity to mental illness than do other children reared differently. Infants reared under apparently inadequate or harmful circumstances do not necessarily develop psychological disorders.

5. Resemblances between patterns of behavior in children and adults can be explained without the hypothesis of a special impressionability or vulnerability of personality in childhood.

6. The initial immobility and the prolonged physical dependency of children upon adults places them at a special disadvantage in that they cannot readily change their environments to obtain new experiences. A lack of new experiences may give to the personality a pattern which appears more fixed than it really is.

The assumption that the human personality is more plastic in infancy and childhood than in adulthood remains unproven. Neither is it disproven. We need much further research in this area and this research may eventually show that the human personality is more plastic during childhood in some respects, but not in others.

DUPLICATION, DOUBLE ORIENTATION AND FUSION¹

MAX LEVIN, M.D.²

In a recent article(4) it was pointed out that disorientation is not a uniform phenomenon, always following the same pattern, but that its pattern varies depending on its cause. The disorientation of toxic delirium differs from that seen in some cases of schizophrenia, which in turn differs from that seen in some cases of brain tumor.

Duplication and double orientation are among the symptoms that have come under study in consequence of the recent surge of interest in the more complex manifestations of tumor and other cerebral lesions. As an example, a patient at the Mt. Sinai Hospital (7) thought there were two hospitals of that name, the one in which she was at the moment being four blocks from home. In reality she lived six miles from the Hospital.

Three cases will serve as a starting point for this discussion:

1. Kubie(1) made an observation in Penfield's operating room. While counting slowly from one to 10 the operator stimulated "a certain temporal area," whereupon "the patient said, 'Now the numbers seem to be doubled,' an impression which ceased the instant the current was discontinued, the impressions fusing at once and becoming, in the patient's words, 'single and clear.'"

2, 3. Weinstein, Kahn and Sugarman's(7) patient M. S., who had a brain tumor, had a son William whom she usually called Bill. She now said she had twin sons, Bill and "Willie." Another patient had one living sister Margaret, nicknamed Maggie, and now she said she had two sisters, Margaret and Maggie.

Kubie's observation throws light on the function of fusion. A sound excites two auditory reception areas, one in each temporal cortex, but we hear *one* sound, not two, because a higher coordinating mechanism "fuses" the substrates of the two auditory images. If we disturb ocular fusion by dislodging the axis of one eye, we see double. In Kubie's case the stimulation caused the patient to *hear* double.

The double hearing occurred on stimula-

tion. Does this mean that the area stimulated contains a "center for duplication"? This would be nonsense (and Kubie, of course, makes no such assertion). A center for duplication is inconceivable. The stimulation must have acted negatively, throwing a fusion mechanism out of kilter.

The effects of stimulation are not always positive. They may also be negative, an example being the unconsciousness of an epileptic fit. Physicians, like other people, are prone to take for granted things that are commonplace. It is a measure of Hughlings Jackson's insight that he recognized that the unconsciousness of an epileptic fit cannot be dismissed as something too obvious to need explanation, that on the contrary it is a paradox. Since the fit results from too much excitation, why, he asked, isn't the patient, if anything, "*hyperconscious*"? In answer to this question he said that the highest cerebral centers, the "organ of mind," cannot function properly when excitation is unbridled and lawless. The neural substrates of ideas and images are complex, and their function presupposes an orderly and harmonious sequence of excitations properly timed and coordinated. He suggested an analogy. If one might suppose a "locomotor center" in the brain, an epileptic discharge therein would not cause the patient to run fast; on the contrary it would bring locomotion to a halt, for locomotion demands a harmonious pattern of excitation in proper time and sequence.

There comes to mind the analogy of a legislative assembly, that does its work by means of orderly parliamentary procedure and decorum. The members speak one at a time. If everyone talked and shouted all at once the result would be, not quicker action, but paralysis of action.

And so in Kubie's case the stimulation must have acted negatively, interfering with the action of a fusion mechanism.

Fusion is involved also in the cases of Weinstein, Kahn and Sugarman already cited. If a man has a sister named Margaret and nicknamed Maggie, he normally would

¹ From the department of neurology and neurosurgery, New York Medical College, Flower and Fifth Avenue Hospitals, New York City.

² Address: 350 Central Park West, New York 25, N. Y.

know that "sister Margaret" and "sister Maggie" are one. In these two cases the relevant fusion mechanism was paralyzed by disease.

Normally one can tell whether an incongruity is real or only illusory. John Smith is a son, and also a father, but only a sick man would say this is incongruous and there must be two John Smiths.

Thus faulty thinking can come from an insufficiency of fusion. It can also come from *too much* fusion. Some patients fuse concepts that should be kept separate. They fail to differentiate. They may fail to differentiate symbol and object. Thus a schizophrenic woman in a mental hospital, speaking of a movie actor whom she admired, said, "He was smiling at me." Inquiry showed she had been sitting in the day room opposite someone who was holding up and reading a movie magazine whose cover bore a picture of the smiling actor. She failed to differentiate the man from his symbol, the picture. Children pass through such a stage. Seeing a picture of a toy in a book, they will try to lift the toy out of the page. Patients who fail to differentiate symbol and object, abstract and concrete, shadow and substance, figurative and literal, etc., show a loss of the "capacity to split" (2, 3).

Hamlet understood all this. He took pains to assure his listeners that he knew a hawk from a handsaw (*handsaw*: a corruption of "heronshaw" or heron).

Adaptation requires two things. We must differentiate, or "split," things that are separate though they look alike. We must also fuse things that are one though they look different; we must recognize that sister Margaret and sister Maggie are one. To paraphrase the Preacher in *Ecclesiastes*, there is a time to split and a time to fuse.

We turn now to a more complex instance of duplication, exemplified by the patient who said there are two Mt. Sinai Hospitals, one in Manhattan (correct) and the other near her home in another borough, the Bronx. This is more complex than the Margaret-Maggie duplication. In the latter instance the patient did not invent anything: sister Margaret and sister Maggie were realities and she erred only in failing to recognize their unity. By contrast, in the former the

patient invented something that does not exist, for there is no Mt. Sinai Hospital in the Bronx.

The key to this duplication of the Mt. Sinai Hospital lies, I submit, in the association of ideas. No concept can be fully understood in terms of its literal definition. The term "Mt. Sinai Hospital" can be defined in just a few words, but its meanings and implications to a sick man would fill a volume. There is almost no limit to the associations that surround even the simplest of concepts, let alone such affect-laden concepts as mother, father, wife, child, home, and hospital. The hospital, which people dread, is yet a refuge, a place which offers relief from pain, and so is associated with home, mother, and similar concepts. This association finds its ultimate expression in the delirious patient who mistakes the hospital for his home (though I do not mean to say that this is the explanation of the misidentification). Perhaps the invention of a Mt. Sinai Hospital in the Bronx is an intermediate step in this direction. It may be significant that as Weinstein and his associates as well as Paterson and Zangwill (6) and Nathanson, Bergman and Gordon (5) have found, in duplication of place in respect of the hospital, the phantom hospital is usually closer to home than the real one.

It is clear that tumor and other cerebral disease can interfere with the action of fusion mechanisms, causing duplication from failure of fusion of two related images. Fusion is a complex function, as complex as the artistic skill that enables the members of an orchestra to play as one man. Loss of fusion reminds one of a team of horses that operate in unison with the aid of a coordinating mechanism consisting of shaft, reins and halters, without which they would act as two.

The question arises: Why only duplication? Why don't some patients say there are three Mt. Sinai Hospitals, or four or a dozen? The answer can only be surmised. Perhaps it has to do with the fact that there are two cerebral hemispheres. The substrate of an image is a complex thing which is certainly not localized in a small cerebral area but takes in the greater part of one or both hemispheres. The existence of duplication shows that there is "room" for the simul-

taneous activation of the substrates of two related images—perhaps one substrate primarily if not entirely in each hemisphere. Perhaps the activation of two such substrates keeps enough cerebral tissue “busy” to preclude activation of a third.

NARCOTIC BONDAGE¹

A GENERAL THEORY OF THE DEPENDENCE ON NARCOTIC DRUGS

SANDOR RADO, M.D.²

The large number of narcotic drugs that can throw the patient into narcotic bondage produce a correspondingly sizeable variety of clinical pictures, each with certain fundamental characteristics common to them all. As the severity of the disorder increases, the conspicuous differences traceable to the chemical individuality of each drug tend to recede, and the clinical picture comes to be uniformly dominated by the same essential pathology. This fact suggests that we need first a general theory of narcotic bondage, that will in turn lead to the construction of a special theory for each drug or group of drugs. After a preparatory study in 1926 (1a), in 1933 (1b) I attempted to evolve a general theory of the dependence on narcotic drugs, using Freud's libido theory as my conceptual framework. This paper proposes to re-examine the subject in the light of added experience and from the point of view of adaptational psychodynamics (2).

Under this revised system of psychoanalytic thought, dependence on narcotic drugs is regarded as a malignant form of miscarried repair artificially induced by the patient himself. Since our chief investigative concern is motivation, let us first find out what the patient believes the drug does for him. If we can win his trust and confidence, he gives us the following invaluable information: "it puts an end to my despair; it makes me feel happy; it restores my self-confidence; and, it does all this in a moment, without any effort on my part. The drug is a miracle. I cannot live without it."

We often find that at the time the patient first took the drug, he was in a state of depression. Suffering from a prolonged illness or from reverses in life, he felt he was unable to make a go of it. He blamed himself and

others, sometimes even the one he loved most; embittered, he desperately longed for miraculous help. This prodromal depression is a precipitating etiological factor, because it sensitizes the patient to the psychodynamic action of the narcotic drug.

By removing pain, relaxing inhibitory tensions, inducing pleasure and facilitating performance, narcotic drugs produce a narcotic pleasure-effect. Conversely, every drug which produces this effect must be classified as narcotic. The average patient, upon therapeutic administration of the drug, responds to its pleasure-effect with a sense of relief and satisfaction. But the patient who is about to develop drug dependence behaves differently, presumably because he has a special predisposition which may be twofold, biochemical as well as psychodynamic. In any case, he has a long previous history showing marked intolerance and fear of pain, and strong though often overcompensated dependency needs indicative of a lack of emotional maturity and security. Sensitized by his depression, he sees in the narcotic pleasure-effect fulfillment of his longing for miraculous help, and responds to it with a sense of personal triumph, a surge of overconfidence: he gets drunk with success. We call this exalted reaction narcotic intoxication or narcotic elation. It is of utmost importance to realize that narcotic intoxication is not limited to alcohol, but is equally characteristic of all narcotic drugs whose misuse society condemns, thereby forcing the patient to hide his elation—as much as possible even from himself.

Scrutinizing the patient's history, one sees that frequently a single experience with narcotic elation suffices to set up in him a narcotic craving of extraordinary and ever growing strength. To explain this remarkable reaction, we must penetrate into the deepest and oldest strata of the mind formed during the early stages of ontogenetic development.

The young organism's first image of itself

¹ Read before the 47th annual meeting of the American Psychopathological Association, February 22-23, 1957, New York City. The topic of this annual meeting was: "Problems of Addiction and Habituation," its proceedings will be published in fall by Grune & Stratton, Inc., New York.

² Address: 50 East 78th St., New York 21, N. Y.

is of proprioceptive (kinesthetic) origin. Enchanted by its ability to move, it attributes unlimited power to its intentional actions and pictures itself as an omnipotent being. This self-image constitutes the representation of the total organism at psychodynamic levels and presides over the integration of its behavior: we call it the primordial self. From this vantage ground the infant views his parents, upon whose ministrations he depends for his survival, as deputies who exercise his magic powers for him.

The grown organism lives under a more or less realistic system of self-government presided over by an adjusted though lovingly retouched self-image called the tested self. This image derives from and inherits the organizing functions of the primordial self, which now has become the hidden core of the organism's desired self, the secret aim-image of its most deeply repressed aspirations.

If in the adaptive struggle for existence self-government fails, the organism may seek to strengthen its tested self with regressed features of its primordial self. However, such repair work is bound to miscarry, since the resulting aggrandized self-image can only undermine realistic self-government.

This also applies to the intoxicated patient. The sudden change from pain to pleasure, from inhibition to facilitation has proved to him by the full weight of an actual experience that, after all, he is the omnipotent giant he had always fundamentally thought he was. One may be tempted to view the patient's grandiose picture of himself as a harmless illusion bound to collapse as soon as the wave of elation subsides. However, closer examination of the clinical facts leads to a different conclusion.

Narcotic elation is followed by sleep and in turn by the morning after. The patient's depression returns deepened by fresh guilty fears and made more painful by the contrast. Yesterday he was a giant to whom responsibilities looked small; today he is small and his responsibilities loom in gigantic dimensions. His situation is worse than before; he feels he must recapture yesterday's grandeur by taking another dose. Thus his craving for elation develops. Augmented by com-

comitant physiological changes, it builds up in him ever-increasing tensions which can be discharged only by means of a fresh elation. Henceforth, every phase of elation leads to a phase of narcotic craving for elation, thence to taking the drug, which brings forth another phase of elation, and so forth in a cyclic course. A narcotic system of self-government, founded on dependence on the intoxicating drug, is established.

The interdependent phenomena of elation and craving for elation show that the patient's grandiose idea operates with delusional strength. This interpretation is further corroborated by the patient's subsequent behavior: he ignores the difficulties and hardships to which he will soon be exposed. To begin with, failure of the pleasure-effect forces him to combat his rising physiological tolerance to the drug by increasing the dose to quantities which he may find hard to obtain. He may be visited by illness after illness resulting from the drug's toxic side-effects. The intoxicating pleasure-effect of the drug diminishes his appetite for food and often destroys his capacity for standard sexual union. His relatives and friends implore him to stop and save himself from certain ruin. While aware of these facts, he nonetheless insists on taking the drug. In an unguarded moment he gives away his secret: "Nothing can happen to me." Though his powers of reasoning and judgment appear to be otherwise unimpaired, he believes unshakably in his personal invulnerability and immortality. The patient's image of himself as an omnipotent and indestructible giant must be clinically described as a thinly veiled narcotic delusion of grandeur rooted in the drug which has produced the intoxicating pleasure-effect for him.

Paradoxically, even conscience tightens the patient's grip on his drug. His guilty fears and self-reproaches, strengthened by his defeated rages turned against himself, elicit automatic acts of expiatory self-punishment. To placate his conscience, his unconscious mind thus drives him to self-destruction by means of the drug (3). His conscious mind does not object because it believes that nothing can happen to him. Under the sway of its primordial self, the organism can unconsciously behold its own march to death.

So far, we have traced the development of narcotic bondage through presumed predisposition, sensitization, narcotic pleasure-effect, intoxication, craving for elation, delusion, and failure of conscience, deriving this pathology from clinical observations; to complete our theory, we shall now examine the relation of this pathology to the organism's hedonic organization.

In adaptational psychodynamics we view the organism as a biological system operating under hedonic control(4). From the evolutionary point of view, hedonic self-regulation must be considered as a very early and fundamental feature of animal organization, perpetuated, like sexual reproduction, throughout the course of phylogenetic history. The pattern of hedonic self-regulation is already foreshadowed in the protozoa: the organism moves towards the source of pleasure and away from the cause of pain. It relies on the expectation that pleasure signals the presence of needed supplies or of conditions otherwise favorable to its survival; and pain the presence of a threat to its organic integrity. Hedonic self-regulation worked because primitive species survived and evolved into higher ones; where it failed the organism (species) died. In our species, it is firmly established at the hedonic level which is fundamental to all levels of psychodynamic integration.

Hedonic control extends over the entire life process as evidenced by the following elementary facts about the human organism: 1. its emergency control is based on the effective use of pain as a warning signal of damage(5); 2. in its pursuit of prosperity, effort and performance are spurred by the pains of deprivation, and are directed, facilitated and rewarded by a variety of pleasures; at the physiological level, the search for and the intake of food are accompanied by pleasures climaxing in satiation called alimentary orgasm(6); at the cultural level, activities toward cultural self-realization are greatly eased by the joys of performance culminating in the self-satisfaction of pride; 3. its primary incentive for reproduction is sexual orgasm attendant upon insemination, the act of integration which renders evolutionary sex differentiation biologically effective(7); 4. its conscience and conduct are shaped by an educational system based on

reward and punishment, that is, on bestowing pleasure and inflicting pain(8).

Hedonic self-regulation advances from a biological to a cultural stage of development. In the infant, its design is still much the same as in subhuman species; however, during the period of growth and maturation this innate design undergoes highly significant cultural adaptations reflecting the cumulative influence of intelligence and learning, education and experience. In the last analysis, these cultural modifications of hedonic control are traceable to the increasing power of foresight which forces the organism to accept *delayed* reward in lieu of *immediate* reward. The extent to which such enlightened hedonic responses supplant the purely biological ones, is a measure of the adult's fitness for cultural cooperation.

The "magic" of narcotic drugs lies in their direct biochemical action on the brain, in their by-passing the prerequisite adaptive effort and performance; through this short-cut they surpass nature's ordinary rewards, and, whenever desired, lift the organism from pain to a pleasure intensified still further by the contrast. As a sort of super-pleasure, the drug's effect makes an irresistible appeal to the organism's hedonic control, displacing more and more the ordinary pursuits and rewards of healthy life. As we have seen, this substitution involves three mechanisms: one of super-pleasure, silencing the warning signals of danger; another of intoxication, ushering in a delusion which, uprooting the patient's reason, foresight and judgment, sanctions his craving; and a third, of conscience, paradoxically promoting the patient's narcotic self-destruction. And yet, viewed in the context of hedonic control, it is only a supporting part that these mechanisms play. The essential factor in the pathology of narcotic bondage is corruption of the organism's hedonic control by the super-pleasure of narcotic drugs. By wiping out the adult's enlightened hedonic responses, the absolute priority of super-pleasure reduces self-regulation to the precultural hedonic responses of the infant, aimed at immediate reward. In other words, corrupted hedonic self-regulation inevitably dehumanizes the patient's behavior: it is on this ground that we consider narcotic bondage a malignant disorder.

By tracing this delusional disorder to its biological roots, we have carried its psychodynamic analysis to the threshold of physiological correlations. During the last year or two, physiological experiments on animals have led to the discovery of "pleasure centers" in the brain, unexpectedly confirming our own hedonic theory. Electric stimulation of these centers gives the animal a unique pleasure reward strikingly similar to the super-pleasure induced biochemically by narcotic drugs.

Let me quote from a 1956 paper by James Olds (9). Using the Skinner method, animals with implanted electrodes were put into a "do it yourself" situation, where, by pressing a lever, they could stimulate their own brain. Dr. Olds says:

The animals seemed to experience the strongest reward or pleasure from stimulation of areas of the hypothalamus and certain mid-brain nuclei—regions which Hess and others had found to be centers for control of digestive, sexual, excretory and similar processes. Animals with electrodes in these areas would stimulate themselves from 500 to 5,000 times per hour.

Electric stimulation in some of these regions actually appeared to be far more rewarding to the animals than an ordinary satisfier such as food. . . . Indeed a hungry animal often ignored available food in favor of the pleasure of stimulating itself electrically. Some rats with electrodes in these places stimulated their brains more than 2,000 times per hour for 24 consecutive hours.

Experimental animals may become even more dependent on the super-pleasure of electric stimulation than do human beings on the super-pleasure of narcotic drugs. Whether or not animals also develop an analogous delusion for the exclusion of their natural life interests is an unanswerable question. But we do know that in the human organism, equipped with a vastly more complex brain, surrender to a corrupted hedonic self-regulation is brought about by the compelling means of a delusion.

In juxtaposition to James Olds' report, I would like to quote a few brief passages from 2 earlier papers of mine. The first was published in 1926(10):

When a person adopts the practice of pharmacotoxic gratification, momentous consequences ensue to his whole psychic and somatic condition. The phenomena presented to the clinical observer in cases of morbid craving are so multitudinous that in this brief survey we must confine ourselves to

stressing certain fundamental characteristics. The changes are enacted principally, of course, in the abode of the libido, for erotic gratification by means of drugs is a violent attack on our biological sexual organization, a bold forward movement of our "alloplastic" civilization. Let us confine ourselves to morphinism and to the most "fashionable" method of administering the poison by means of the Pravaz syringe. To put the matter in a nutshell, the whole peripheral sexual apparatus is left on one side as in a "short circuit" and the exciting stimuli are enabled to operate directly on the central organ. I propose to term this phenomenon, which deserves to be distinguished by a special name, "metaerotism." With the advance of organic chemistry the manufacture of the most refined substances for producing sexual gratification is assuredly only a matter of time, and it is easy to prophesy that in the future of our race this mode of gratification will play a part as yet uncalculable.

In 1933 I wrote(11):

What is immediately evident is the fact that the pharmacogenic attainment of pleasure initiates an artificial sexual organization. . . . The pharmacogenic pleasure instigates a rich fantasy life; this feature seems especially characteristic of opium-pharmacothymia. . . . The crux of the matter is, that it is the pharmacogenic pleasure-effect which discharges the libidinal tension associated with these fantasies. . . . The genital apparatus with its extensive auxiliary ramifications in the erotogenic zones falls into desuetude and is overtaken by a sort of mental atrophy of disuse. The fire of life is gradually extinguished at that point where it should glow most intensely according to nature and is kindled at a site contrary to nature.

We must remember that in the libido theory such terms as "libido," "sexual" and "erotic" were (and still are) used in a "wider sense" denoting desire for and love of pleasure, which might be non-sexual as well as sexual(12). Accordingly, "sexual organization" meant "pleasure organization," "peripheral sexual apparatus" meant "peripheral pleasure apparatus," etc. The appropriate name for the phenomenon I called "metaerotism" is "metahedonism." The point is that these early formulations firmly established the intoxicating pleasure-effect as the key to the psychodynamic action of narcotic drugs and, in the long view, as a threat to the future of our species.

Generally speaking, the prognosis of narcotic dependence is unfavorable, and the problem of rehabilitation extremely difficult. The crux of the matter is that the patient does not suffer from his illness; he enjoys it. Even if we succeed in influencing him

for a short time, we cannot expect his sustained cooperation. This attitude, consistent with his pathology, determines the plan for rehabilitation. The first task is to win the patient's consent and withdraw the drug, preferably in a specially equipped hospital and with psychotherapeutic support. Afterwards the patient should go on with psychotherapy, if possible while remaining in the hospital until the potential dangers of violence, suicide and relapse are sufficiently reduced. Without entering into the technical details of this delicate procedure, I wish to stress that its most effective component is the release of the patient's defiant rages and embittered resentments, restoring his self-respect and human dignity.

Aside from such protective measures, at this stage the decisive problem is the underlying disorder which first prompted the patient to cast his lot with the drug and which now will cause him to feel tempted again and again. We may divide our patients into three groups. In the first, drug dependence was precipitated by a so-called psychoneurosis or, in our terms, an "overreactive" or "moodcyclic" disorder; in the second, by a schizophrenic process; in the third, by the impatient agitations of a frustrated psychopath (the "extractive type" of our classification).

Of these three groups, we can make recommendations only concerning the first. Here the preferred method is reconstructive psychoanalytic therapy. The outcome depends upon the patient's inner resources and his life circumstances.

The belief that withdrawal of the drug alone suffices to free the patient from his bondage has unfortunately no foundation in fact. While it is difficult to gather dependable statistics, the available information indicates that the majority of the patients relapse within a few months and the remainder within a few years.

May I say a word about the future as I see it? Though the essential prerequisite for rehabilitation, withdrawal of the drug is a precarious procedure. The ideal solution would immunize the patient against the intoxicating pleasure effect of narcotic drugs. The last few years have brought us the beginning of a physiology of pleasure; we may

now look forward to a physiology of the narcotic pleasure-effect. By viewing the narcotic super-pleasure as a developmental derivative of alimentary orgasm, psychodynamics may even offer a clue to the search for its biochemical mechanism (13). I believe it possible that eventually biochemists will discover a method for the immunization of the organism against the narcotic pleasure-effect. Even if this hope materializes, shutting off escape into drug dependence, the patient will still be left with the problem of his underlying disorder.

Let me sum up. To achieve clarity, in our general theory we have separated the pathology of drug dependence from the pathology of the underlying disorder, applying to both the insights of adaptational psychodynamics. In this light, drug dependence is seen to be a self-inflicted process of miscarried repair; it transforms realistic self-government into narcotic self-government. Utilizing our previously suggested concepts of narcotic pleasure-effect, narcotic elation and narcotic craving for elation, we have shown that both elation and craving for elation are interdependent manifestations of a thinly veiled narcotic delusion of grandeur elicited by and rooted in the intoxicating pleasure-effect of the drug. This chain of pathological events was then traced to corruption of the organism's hedonic self-regulation by the effortless and instantaneous super-pleasure of narcotic drugs. Trapped by the subversive super-pleasure, the patient abandons his enlightened hedonic responses based on delayed reward, and reverts to the precultural responses of the infant, aimed at immediate reward. It is this dehumanizing consequence of a corrupted hedonic control that makes drug dependence a malignant disorder. Our hedonic theory of this disorder first outlined in 1926 and 1933 now finds striking corroboration in the animal experiments of James Olds concerned with the demonstration of "pleasure centers" in the brain.

From this malignant pathology we deduced the plan for rehabilitation: withdrawal of the drug; supportive and reconstructive psychotherapy whose goal is control of the potential dangers of violence, suicide and relapse, and, whenever feasible, eradication of the underlying disorder. Finally, we called

attention to the need for further advances in the physiology of pleasure, which may well open the door to the patient's expected biochemical immunization against the intoxicating pleasure-effect of narcotic drugs.

DETECTION OF CHLORPROMAZINE IN BODY FLUIDS

D. J. CAVANAUGH, PH. D.,¹ AND FRANK R. ERVIN, M. D.²

The oxidation of chlorpromazine or its metabolites in strong acids serves as the basis for both quantitative(1) and qualitative(2) analytical methods. Color development in a sulfuric acid medium may be promoted by the ferric ion(2).

The rapid development of color in sulfuric acid is attended by the disadvantages that 1. the color is unstable, 2. naturally occurring chromogens may give considerable interfering color, 3. the ferric ion is highly colored, and 4. the reaction is limited to use with protein-free solutions. These difficulties may be avoided by using concentrated (85%) phosphoric acid as the solvent. The color developed in H_3PO_4 is relatively stable, natural chromogens are less highly colored, the ferric ion is present as a colorless complex, and all proteins tested give optically clear solutions with no tendency toward turbidity.

In H_3PO_4 chlorpromazine itself forms a red product having an absorption maximum at about 530 $m\mu$. Chlorpromazine sulfoxide yields a violet product which has an absorption maximum with its midpoint at 540 $m\mu$. Spectrophotometric examination of the urinary forms of the drug indicates that the predominant metabolite is the sulfoxide. This is in agreement with the reported metabolic disposition on the drug(3) and qualitative tests on urine should be run in comparison with the sulfoxide rather than pure chlorpromazine. Urine from patients receiving doses of the order of 200 mg. or more per day usually develops a strong violet to purple color in phosphoric acid alone and addition of ferric chloride is unnecessary.

When the ferric ion is used to accelerate color development one must exercise caution. The ferric ion has a well known tendency to form complexes with phenolic compounds and it is particularly reactive as a complex-forming ion with respect to salicylic acid and some of its derivatives. The validity of tests for chlorpromazine is dependent upon the

elimination of various drugs as sources of interference. Notable among these is aspirin. Urinary derivatives of acetylsalicylic acid may include free salicylic acid as well as certain conjugated products of varying susceptibility to acid hydrolysis(4).

The procedure adopted in this laboratory is as follows: urine is mixed with 85% H_3PO_4 in the ratio 1:4. Within an hour color development is noted if the sample collection is made within 8-12 hours of the drug administration. When very small doses (of the order of 25 mg.) are given the color is feeble and considerable care must be taken to avoid confusion with color arising from natural chromogens. In such cases ferric chloride may be added to promote color development. Usually 0.1 ml of 1M ferric chloride to 5 ml of the test mixture is adequate. This test may be applied to cerebrospinal fluid or serum without interference due to turbidity. In the latter case the authors were unable to detect more than traces of chlorpromazine within 30 minutes of the i.v. injection of as much as 200 mg. of the drug. No positive test on cerebrospinal fluid has yet been obtained. Direct sunlight should be avoided in performing this test. Color development may not be complete for several hours when drug concentrations are low and it is advisable to re-examine the test solutions four or five hours after mixing the acid and urine. There appears to be no interference by reserpine. Reducing agents bleach the solutions, particularly when the ratio of water: acid is too high. The ferrous ion is very effective in this respect and photoreduction of the ferric complex undoubtedly hastens bleaching when the ferric chloride-containing solution is exposed to strong light.

CEREBROSPINAL FLUID NEURAMINIC ACID DEFICIENCY IN SCHIZOPHRENIA

A PRELIMINARY REPORT

SAMUEL BOGOCH, M. D., PH. D.¹

The neuraminic acid content of cerebrospinal fluid² was determined in individual specimens obtained in random diagnostic lumbar punctures performed on 90 general hospital patients, both children and adults, and 30 mental hospital patients, none of whose diagnosis was known. When the records were later consulted, 17 of the mental hospital patients were found to have the clinical diagnosis of schizophrenia. The mean content of the schizophrenic patients was found to be lower than that of non-schizophrenic mental hospital patients, and even lower than that of children under 7, whose mean value was much below that of the adult.

	Age in years	Number of patients	Neuraminic acid, in microgram/cc. C.S.F.	
			Median	Mean
Schizophrenic patients	20-62	17	37.5	36.6
General hospital children	0.2-6	54	41.0	42.7
General hospital children	7-16	26	46.0	46.2
Non-schizophrenic mental hospital patients	16-61	13	50.0	53.0
General hospital adults	27-57	10	56.0	61.5

Only 2 of the 17 patients diagnosed as schizophrenic had values above 40 (43 and 49). Only 4 of the 49 'non-schizophrenic' patients over the age of 7 had values below 40 microgram per cc. (37.0 in each case), but the examination of the clinical records of these 4 revealed that one was a 23-year-old male diagnosed as "obsessive-compulsive" who had had 3 mental hospital admissions; the second was a 13-year-old girl whose condition was diagnosed in a general hospital as 'conversion hysteria' because of 3 attacks of

a negativistic coma-like state; the third was a 40-year-old severe 'psychoneurotic' who had been under psychiatric care for many years; and the fourth was a 12-year-old boy with no history of mental disorder.

While the number of patients studied does not permit any conclusion regarding the diagnostic value of this determination, the results to date would appear to indicate an important new area for further investigation. Thus, the tendency for the concentration of neuraminic acid to increase with age suggests a relationship to maturation. Low values in certain adult schizophrenic patients, comparable only to those found in some children under 7, might indicate a form of chemical immaturity.

Recent studies in this laboratory(1-3) have led to the development of the hypothesis(4) that the neuraminic acid-containing substances of both brain and cerebrospinal fluid, i.e. gangliosides, glycoproteins, and other conjugates, are involved in a "Barrier-Antibody System," which is concerned with the isolation of the brain from substances which pass readily from the blood to other tissues. This term includes, in addition to the classical notion of a fixed blood-brain barrier, an immunochemical concept of a circulating cerebrospinal fluid component. The Barrier-Antibody System may be inadequately developed in the schizophrenic.

Micromethods which have been developed for the quantitative analysis of individual specimens of cerebrospinal fluid with regard to the distribution of neuraminic acid between small and large molecular weight components, are described in the detailed report of this work(4).

POSSIBLE SYNERGISTIC ACTION OF CHLORPROMAZINE, RESERPINE AND FRENQUEL. A PRELIMINARY REPORT

J. WILLIAM SILVERBERG, M.D., AND ALEXANDER GRALNICK, M.D.¹

With the addition of an increasing number of ataraxics to our armamentarium there are numerous clinical reports as to their effectiveness, special uses, dosages and toxic side-effects in the literature. A number of workers have reported their experiences with a combination of chlorpromazine and reserpine. We have recently begun using a combination of chlorpromazine, reserpine and frenquel. The results have been sufficiently interesting to warrant a preliminary report to bring them to the attention of the profession in hopes that other workers will try and report on the effect of the combination.

The work reported was done at High Point Hospital, a private mental hospital, where intensive psychotherapy is the cornerstone of the therapeutic program. It has been our experience, as has been reported by many others, that the ataraxics, particularly Thorazine and Serpasil, are of great help in bringing psychotic patients into meaningful psychotherapeutic relationship. Our experience with Frenquel, used in a similar way, has on the whole been discouraging. A combination of the three drugs has given surprising results. Most of these patients were highly recalcitrant to treatment and some had been treated with chlorpromazine, reserpine and Frenquel separately without significant effect.

CASE REPORTS

1. A 40-year-old, married schizophrenic woman had her first psychotic break 10 years ago and this her fourth hospitalization, occurred after a year's gradual downhill course on intensive (three times a

week) ambulatory supportive psychotherapy. Shortly after admission she became confused and suspicious on her ward, and almost totally uncommunicative in psychotherapy. She was treated with chlorpromazine 100 mg. t.i.d. and reserpine 3 mg. t.i.d. for 3 weeks without apparent effect, and then Frenquel 40 mg. t.i.d. was added to these medications. Within a few days there was definitely more responsiveness towards personnel, and in psychotherapy she began to express her paranoid delusions. After 2 weeks she had begun to drop her delusions and these have not occurred. She has been able to work actively in psychotherapy.

2. An 18-year-old paranoid schizophrenic girl had received extensive ECT and insulin treatment before hospitalization at High Point. During her 8 months in hospital she had shown little response to psychotherapy, nor had ECT or Thorazine, used individually, affected her favorably. She was placed on chlorpromazine 100 mg. q.i.d., reserpine 2 mg. q.i.d., and Frenquel 40 mg. q.i.d. and within 4 days began to relate her paranoid delusions to her therapist. Two weeks later she dropped these ideas as "silly and sick" and has not resumed them. Although previously she had resisted taking medication, she now takes it willingly. After about 5 weeks on the 3 ataraxics, she began to show signs of slipping back to her former condition. The medications were stopped and her condition deteriorated. When 2 weeks later the medications were resumed she repeated the good response she had shown before.

Although the total number of patients treated thus far is still small, we feel that the fact that several patients, who have been in a chronic, highly static state for months, have shown significant improvement warrants this preliminary report. Although we have varied the total amount of medication given in various cases, i.e. chlorpromazine 200 mg., reserpine 2.0 mg., Frenquel 20 mg. daily, to chlorpromazine 400 mg., reserpine 4 mg. and Frenquel 160 mg. daily, the approximate proportions have been maintained constant.

PERPHENAZINE—A DRUG MODIFYING CONSCIOUSNESS

N. L. MASON-BROWNE, M.A., M.B.¹

Since it is increasingly necessary that satisfactory evidence of the efficacy of drugs be

¹ Crease Clinic of Psychological Medicine, Esson-dale, B. C.

available before those drugs are prescribed, a preliminary study of one of the newer agents has been carried out. This paper represents a brief report of this study, the re-

sults of which will be published later in greater detail. The drug, perphenazine (Trilafon),² is an amino-derivative of chlorphenothiazine and may be assumed to act upon the alerting system of the brain stem. Animal experiment demonstrates that its potency is 5 to 10 times that of chlorpromazine.

A total of 75 chronic patients (36 men, 39 women) was used. All displayed anxiety, over-activity or were problems in nursing management. The author personally tested all the patients, who were divided into three equal groups and were retained in their usual setting. The double blind technique was employed. One group was given perphenazine 16 mg. t.i.d. by mouth, a second group of 25 received 25 mg. chlorpromazine t.i.d., and the last group had 25 mg. placebo t.i.d. All three tablets were exactly the same in shape, size, and colour, although not in effect, and were given over a 30 day period. Urinary, blood, and liver function tests were carried out before and after the trial. Nursing records of blood pressure, pulse, respiration, nausea, restlessness, anxiety, alertness, confusion, and appearance of insomnia were kept daily. A quantitative evaluation of behaviour (acute anxiety cluster of the Wittenborn Rating Scale) was used to rate patients before and after the trial. On these occasions each patient was also submitted to a battery of tests chosen as measures of attention, concentration, memory, learning, and basic perceptual and motor function. Tests used were the Tapping, Dotting, Digit Symbol, Digits Forwards and Backwards, and Porteus Maze.

² Trilafon is the trade name of Schering Corporation Ltd. for perphenazine.

Side-effects occurred in 7 of the patients receiving perphenazine and in no others. These took the form of Parkinsonian signs and increased secretions. Hypotension and altered liver functions and allergic side-effects were not found.

Patients receiving perphenazine showed greater improvement in the tests which measured integrative function below the cortical level, and yet above the multi-neuronal reflex level. Tapping and dotting showed the only statistically significant variation in performance. The source of variation was significant for perphenazine but not for chlorpromazine. Insofar as the other tests which we assume measure higher-order function did not show significant differences, it may be postulated that the site of action of the drug is at the subcortical level.

Maze results were not statistically significant, but showed a decrement of performance similar to that following psychosurgery. The Rating Scale for anxiety also showed a statistically significant variation for perphenazine but not chlorpromazine.

Rating testing and clinical assessment showed perphenazine to be similar in action to chlorpromazine, but with greater efficacy and more favourable therapeutic ratio. Un-toward side-effects occur with its use, but may be avoidable with smaller doses, and are easily controlled.

The term "tranquilizer" is a misnomer and also has numerous unfortunate implications for lay persons. Since these drugs affect crude or basic consciousness and awareness, the term "sciotic" drug is suggested as an alternative.

RESEARCH NOTES

INVESTIGATION OF THE OEDIPUS PHANTASY BY HYPNOSIS

W. EARL BIDDLE, M.D.¹

The widespread controversy over psychoanalysis is inevitable so long as validation depends upon subjective values, experiences and insights. Psychiatry and medical psychology have been enriched by the contributions of psychoanalysis, but those who insist upon adherence to Freudian orthodoxy tend to discredit the whole movement as unscientific. No entirely objective study is possible within the framework of psychoanalysis itself, but an interdisciplinary approach can be helpful. Hypnotic regression and revivification are valid investigative procedures which provide an objective method of study of human behavior, and are applicable here.

In our study 100 subjects were interviewed at the regressed age level of 3 years, and asked about what they could do by "just thinking" or "magic thinking." These subjects were psychotic (in partial remission), psychoneurotic and normal persons. At first we tried to regress the subjects to oral, anal and phallic stages. This proved impracticable as we could not hold the subjects to an age level. Also, we were suggesting phantasy material tailored according to psychoanalytic theory, and were thereby jeopardizing the validity of our results. We then decided to regress the subjects to a fixed age level and ask them about their own phantasies. This report is limited to the Oedipus phantasy.

All subjects phantasized making themselves small and entering into the body of the parents, or making the body of the parents extremely large so that the subject could go in. This phantasized entrance was made through the skin, the eyes, the ears or any

of the body orifices. It is especially noteworthy that the subjects always entered the body of the parent *in toto*. This bodily union was analogous to a spiritual communion between the parent and child, and did not have the implication of a lustful attachment. Expressions made by the subjects, such as, "getting into mother's body" or "taking father to bed" would quite understandably be misunderstood by most therapists as incest wishes. However, in no instance did the subjects express erotic desires for a parent. When questioned about sexual relations the invariable answer was that children did not have such wishes, and that sexual activity was for adults only. Childlike innocence, however, does not imply ignorance. We found a surprisingly accurate knowledge of impregnation and birth at this age level, but some subjects did not retain this knowledge at a later age level.

When feeling frustrated or neglected the subjects responded with intense hostility to either or both parents. This hostility extended far beyond mere death wishes. The frustrating parent was completely annihilated. This appeared to be accomplished by negative hallucinations. The subjects also phantasized the parents making brutal attacks upon one another and battling to mutual extinction. The ability to create was as preposterous as the ability to annihilate. The subjects handled these abilities with a naive self assurance.

It is concluded that the Oedipus phantasy described by Freud is not found regularly, but children of both sexes strive for a shared spiritual union with both parents.

CORRESPONDENCE

OSCAR WILDE

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: In a recent issue (April, 1957) of this JOURNAL, C.B.F. reviewed *The Three Trials of Oscar Wilde* edited by H. Montgomery Hyde. I have read this interesting book and find Dr. Farrar's review most informative and apt.

In spite of the unusual publicity and attention given to this famous trial and to the subject of homosexual perversion, it is curious—as C.B.F. points out—"no medical evidence was presented that might have thrown light upon Wilde's inversion and perhaps altered the issue of the trials." Many etiologies for Wilde's perversion have been suggested including (1) an abnormal inheritance from his father who was hyper-heterosexual, (2) an abnormal inheritance from his mother who showed acromegalic changes, (3) an abnormal social identification resulting from his mother's practice of dressing him in female clothes as a child, (4) abnormal psychosexual relations from a dynamic point of view to his mother. Not one of these etiologies withstands critical scrutiny. Regarding his father's hypersexuality, it would be a brave critic indeed who after reading Kinsey's report would categorize his father's behavior as beyond the normal range of male sexual activity. Furthermore, where is the evidence for a general transmission of homosexual behavior? Equally vague is the relationship between the acromegalic physique of his mother and Oscar Wilde's inversion. There is a paucity of data which shows that these two are related. The third etiology is effectively discounted by the editor of the book, H. Montgomery Hyde. The fourth proposition is equally tenuous. It is not difficult to highlight focal points in any personal history which can support any given hypothesis provided that (1) the complete history is known, that is, no prediction is required, and (2) that personality history which favours the hypothesis is considered

a fact and personality findings which counter the hypothesis are considered examples of resistance to the underlying true but unexpected fact.

I would like to present yet another theory regarding the etiology of Wilde's perversion and of his trials. It is simply this—that Wilde's inversion and unusual behavior was triggered by a personality change due to an insidious cerebral syphilitic process. As a result of this pathological change, Wilde's brilliant but unfeeling wit for social situations, which, in the climate of his time operated to his success in his plays, led to his downfall as a result of the trial and conviction.

Wilde was born in 1854. He attended Oxford University between 1874 and 1878 where he contacted syphilis from heterosexual relationships. This was treated with mercury but not successfully. He married in 1884.

Editor Hyde states that "We know too that he was deeply in love with his wife at the time of their marriage, and that they experienced normal sexual intercourse. Indeed, two sons were born of the union before the rift between them took place. At the beginning the husband seems to have been an enthusiastic lover. To a friend whom he chanced to meet during the honeymoon he spontaneously expatiated upon the physical joys of wedlock. And on the occasion of his first separation from his wife, some months later, he wrote to her from Edinburgh: 'Here am I; and you at the Antipodes: () execrable fates that keep our lips from kissing, though our souls are one. . . . The messages of the gods to each other travel not by pen and ink, and indeed your bodily presence here would not make you more real: for I feel your fingers in my hair and your cheek brushing mine. The air is full of the music of your voice, my soul and body seem no longer mine, but mingled in some exquisite ecstasy with yours.'

"Before proposing to his wife, Wilde had consulted a doctor in London, who had assured him that he was completely cured of his youthful malady. On the strength of this assurance he married. About 2 years later he discovered to his dismay that all traces of syphilis had not been eradicated from his system, and it was this unpleasant discovery which obliged him to discontinue physical relations with his wife. In the result, *inter alia*, he turned towards homosexuality."

His first trial occurred in 1895, 17 to 21 years after harboring the treponema pallida. This certainly was long enough for the establishment of a syphilitic process in the brain. He died in 1900, and the doctor who attended him in his last days stated that his patient displayed all the symptoms of a chronic syphilitic.

Wilde's behavior before, during and after the trial was brilliant in his use of repartee but woefully lacking in judgment and he effectively demolished his chance for freedom by (1) not being very honest with his solicitor, (2) by falsifying his age (a matter of public record), (3) by withholding information that might have saved him and then feeling martyred because he had done so, and (4) by continuing his first suit against the Marquess of Queensberry against the advice of his good friends. On page 35, Editor Hyde refers to his "temptation to show off." A dinner is described with Shaw,

Douglas and Harison when he was advised by Shaw and Harison to withdraw his suit and quit the country but he refused. On page 43, "Wilde was urged by his friends on all sides to leave the country," but a perverse and foolish sense of obstinacy and bravado induced him to stay at all costs and see the thing through. Again "this line of thinking was reckless in the extreme."

After the first trial, he was again advised to leave England but he found himself in a pathetic state of indecision lamenting that the train had gone or that it was too late, and then feeling that he had at that time a good chance of being acquitted.

Admittedly, this hypothesis suffers from the same difficulty as the earlier hypotheses, that is the lack of adequate medical and psychological data regarding Oscar Wilde. However, in my opinion, the fact of the syphilitic process and the fact of poor judgment late in his life do suggest the hypothesis that if Oscar Wilde had not had cerebral syphilis—(1) he might not have become homosexual, (2) if he had become homosexual, he might have been more circumspect as regards his behavior, and (3), he would have shown much more judgment at the time of his trial and perhaps have avoided the consequences.

A. HOFFER, M. D.,
Director, Psychiatric Research,
University Hospital,
Saskatoon, Saskatchewan.

PERSONALITY

Everyone now believes that there is in a man an animating, ruling, characteristic essence or spirit, which is himself. The spirit, dull or bright, petty or grand, pure or foul, looks out of the eyes, sounds in the voice, and appears in the manners of each individual. It is what we call personality.

—CHARLES W. ELIOT

PRESIDENT'S PAGE

Through the generosity of the Editorial Board, the President has been given the privilege of a page of the JOURNAL to communicate to his associates some of his ideas, ruminations and activities. One of the first jobs of an incoming president is the appointment of committee members. There are approximately fifty active committees, each made up of six or more members; therefore there are somewhat more than three hundred committee members, of whom about one-third finish their tour of duty after three years. The new president thereupon has the obligation of filling the vacancies. This is a major undertaking, as it is desirable that each committee member be interested, devoted and energetic in pursuing the activities of the committee for the welfare of the Association. Geographical distribution is desirable. It is pleasant to report to the Association membership that there is only one declination to accept the committee appointment. The letters of acceptance evidenced great enthusiasm for the opportunity to serve.

When I became a member of the organization (then called the American Psychopathological Association), the membership numbered approximately 800. At an annual meeting, there was, and is expected attendance of 25 to 30 per cent of the membership. Hence 200 to 300 members assembled. It was easy, therefore, to become acquainted with the majority of one's associates. The number of papers was relatively few, as there were no multiple sections. The annual meeting was an event of social significance where one could become acquainted with the activities and ideas of a large portion of the membership. Good fellowship, a forum for the reading of papers and a discussion of the affairs of the Association took place. The meeting was reported in great

detail in the JOURNAL, including reports of committees and actions taken by the Council at its interval assembly. Today the number of members is approaching 10,000. Indeed, in this past year essentially as many new members were elected as the total membership rolls of this earlier period.

Throughout the history of the Association, the membership has taken very seriously the matter of the mental health of the nation, and through its officers and committees has attempted to effect leadership. In recent years, with the rapid growth of membership, with the increased activities in the field of mental health throughout the countries represented by the APA, the responsibilities and the activities have multiplied. The establishment of an organization headed by a medical director has come into being. The new home is shortly to be occupied. This has brought to the Association if not a new orientation at least the responsibility of deciding where it wishes to go, how much activity it wishes to foster, and how expanding activities can be financed. We are faced with the questions inherent in all large organizations of centralization or decentralization. Personally I am devoted to the theory of decentralization. To my way of thinking, it is fortunate that the Association has apparently taken the steps for decentralization side by side with strengthening the central organization. The creation of the Assembly and District Branches, the development of Divisional and Research meetings, suggest a direction of activities that I believe is very hopeful. It is my hope that the activities of the Assembly of the District Branches will develop more and more and become the effective portions of our organization.

HARRY C. SOLOMON, M.D.

COMMENT

THE UPSURGE OF THE SAVAGE

Not so long ago *The Medical Journal of Australia* published an editorial about social conditions representing different cultural levels as between separate racial stocks, and also about primitive traits that come through to the surface in so-called civilized communities.

This editorial said things that are worth retelling and Dr. Mervyn Archdall, Editor of *The Medical Journal of Australia*, has graciously authorized the quotations that follow.

Residents in the more primitive parts of Australia where aborigines are to be found have frequently described their experiences when endeavoring to train an intelligent native girl and bring her up in the ways of white civilization. Often the girl in "pre-teen age" excels her white school-fellows in quick perception and retentive memory; her sponsors are delighted with her progress and predict for her a future of usefulness. But when she has entered the "teenage" the girl becomes restless, especially if any of her people are camping nearby, and then one day she disappears without a word of farewell. When next seen, if she is seen at all, she is a scarred and verminous savage with pendent breasts nursing a baby. The habits of her white sponsors have been shed as a snake sheds its skin; she is happier in her unkempt condition, and any return to the ways of her former life as a foster child is not only impossible but is not desired. We speak with pity of such a reversion and are apt to regard it as a characteristic of the aboriginal and as something from which we are happily exempt, but let us not be too certain and complacent. Mankind has for so many tens of thousands of years indulged in wild magical rites and orgies of sexual license, with stamping of feet to the rhythm of tom-toms, frenzied dancing of warriors and witch-doctors, with gashing of skin and enforcement of hideous mutilations that even in the best of us there are interwoven in our psychic background the predispositions and

sinister potentialities of the savage. Wordsworth wrote that heaven lies around us in our infancy, an aphorism which a mother of a healthy family of young children is hardly likely to accept as true; but Wordsworth proceeds to deplore the fact that shades of the prison house begin to close about the growing boy. Puberty, especially in the boy, not only witnesses the onset of sexual desire and gratification, but a host of turbulent and often antisocial impulses. It is just at this age when he needs vigilant watching and careful guidance that he is too often pushed out into the world to earn a wage and pick up any contamination offered in his environment. We are horrified at the extent and nature of vandalism; upholstery of railway cars is slashed, young trees, carefully chosen and planted, are uprooted or cut down, sacred memorials are desecrated, devices designed for young people's own protection are wrecked and too often acts of sabotage are committed which in a high degree endanger human life, as when obstructions are placed on railway lines. We are often told that education is an asset which is permanent, it cannot be lost or squandered; but, alas, this is not quite true. . . . Like the civilized behaviour of the aboriginal girl brought up in a white home, it is overwhelmed by the upsurge of the savage innate in the growing boy and girl of all races, and liable to take command of character unless deftly held in check. We should keep this consideration always in mind. We read of rock and roll dances in which young folk are carried away by an hysterical frenzy and behave as if demented; they are merely giving way to elemental forces deeply implanted in human nature. Adults simply cannot understand the screaming adulation of crooners and similar entertainers given by silly girls, but these are only reverting to ancestral usages. . . .

Our daily life displays evidences of magic all around us. The mascot, whether a living animal or an inanimate object, is accepted as something giving a human touch to the ac-

tions of the possessor, but is in fact a piece of pure mumbo-jumbo. Revealing of the future by divination is observable in lucky numbers and in tips for horse-racing given by haphazard occurrences and coincidences. Around each lottery there has grown a huge system of unwarranted optimistic beliefs and hopes which lure the prospective buyer of tickets; the hard facts of mathematical theory of probability do not fit in with aspirations based on magical premises.

The great service of Hippocrates to medical science was the divorce of medicine from the supernatural, but, alas, that did not persist as a guiding principle. Soon magic re-entered medical practice and remained until nineteenth century science accepted the challenge and restored the Hippocratic tradition. That is to say, in the ranks of the medical profession magic no longer exerts any influence, but unfortunately this is not true of the lay public which, as the old Latin adage tells us, "likes to be deceived." It is a sad fact that the anxious patient would sometimes prefer a bit of hocus-pocus in the attention

of his family doctor. Often he will renounce the trained medical man and seek comfort in the advice and irrational ritual of the herbalist, faith-healer and quack. To the medical practitioner who is doing his best for his patient this attitude can be very irritating, but it should be remembered that it is merely another instance of the savage within us bursting through the logical confines in which scientific progress has enclosed us. Sooner or later science will win and magic be forced into dark corners; it may take longer than we expect as the powers of darkness are still mighty in human nature. The great practical issue is that not only must we offer good education to boys and girls, but that we should be conscious of this urge to let the elemental savage within us take over the direction of our lives. Precept and example, opportunities for work and healthy recreation are to be consistently offered, whilst in the case of the boy and youth it would be wise if we did not allow reaction against the severe corporal punishments in past times to lead us to the opposite extreme.

HUMAN BETTERMENT

No great improvements in the lot of mankind are possible until a great change takes place in the fundamental constitution of their modes of thought.

—JOHN STUART MILL

. . . and until their biological evolution is much further advanced, he might have specified.

NATURE AND MAN

Nature, generous and heartless, extravagane and miserly as she is, is our Mother and our only teacher, and she is also the deceiver of men. Above her we cannot rise, below her we cannot fall. In her we find the sea and soil of all that is good, of all that is evil. Nature originates, nourishes, preserves, and destroys.

Every brain is a field where nature sows the seeds of thought, and the crop depends upon the soil.

—ROBERT G. INGERSOLL (1899)

OFFICIAL REPORTS

REPORT OF THE COORDINATING COMMITTEE ON THE COMMUNITY ASPECTS OF SOCIETY

COMMITTEE ON ACADEMIC EDUCATION—
Chairman, Bryant M. Wedge: The major project of this committee is to explore resources within and outside the government for the scientific study of problems of youth. As the result of this study there is the possibility of the publication of a survey of these resources for the use of psychiatrists and other investigators. Secondly, the committee hopes to make recommendations for the establishment of an office of scientific, youth information for the collection and codification of source data, the encouragement of research and the publication of accurate scientific data concerning problems in this field. They are working with a representative of the National Institute of Mental Health.

The committee sponsored a roundtable on the International Problems of College Mental Health and a section on psychiatry and academic education at the annual meeting.

COMMITTEE ON CIVIL DEFENSE—*Chairman*, Calvin Drayer: This is a new standing committee added to this coordinating committee group. They are currently involved in a joint project with the federal civil defense administration for the evaluation of mental hospitals in civil defense. This is entirely in the investigative phase and will be carried on during the coming year.

COMMITTEE ON INDUSTRIAL PSYCHIATRY—*Chairman*, Ralph T. Collins: This committee developed an exhibit on industrial mental health which has been shown at various business and professional meetings, most recently at the National Industrial Health Conference held in St. Louis. It is the first time that this topic has been presented at the Industrial Health Conference, and it created a great deal of interest. The exhibit currently is on display at the Kingsport (Tenn.) Mental Health Association Clinic during mental health week.

A brochure on mental health hints for

personnel people is being prepared and will be published within the next year.

There is a great increase of interest in the field of industrial psychiatry both by personnel and management groups as well as psychiatrists. The members of this committee are constantly in demand for talks and meetings with representatives of business throughout the country.

COMMITTEE ON INTERNATIONAL RELATIONS—*Chairman*, Iago Galdston: This committee is concerned with many aspects of our international relations in the field of psychiatry, with our foreign members, foreign guests, and momentarily is very much interested in the possibility of the regional meeting in Florida which would include psychiatrists from Central and South America.

The committee sponsored an afternoon session at the annual meeting on the "Perspectives on International Psychiatry" with five distinguished speakers from foreign countries. Also they arranged a luncheon for our foreign guests and conducted a dinner roundtable on the "Relation of Social Ethics, Religious Principles and Psychiatry" using four distinguished speakers from foreign countries.

COMMITTEE ON COOPERATION WITH LEISURE-TIME AGENCIES—*Chairman*, Alex R. Martin: This committee is thoughtfully considering the preparation of a monograph series dealing with the mental health concerns of leisure. They have obtained a film "Osborn on Leisure," which can be used by the members of the Association as well as leisure time agencies for educational purposes to civic groups. The committee is also considering other methods of the use of mass communication media.

Their major interest is to enlist much further than hitherto the membership of The American Psychiatric Association in giving of their skills and knowledge to

leisure-time agencies, both at the national and particularly at the local level. It is hoped this might be greatly increased through the district and affiliate branches. This particular committee has carried on extensive consultations and conferences with many types of leisure-time agencies, in order that it may be in a more effective position to provide leadership and assistance to psychiatrists who will, at the local level, work with such agencies.

COMMITTEE ON NATIONAL DEFENSE—*Chairman*, Joseph S. Skobba: The Committee on National Defense is continuing its analysis of the survey of medical officer opinion concerning the military program as a career. It is also concerning itself with the steps taken under the MEND program to teach military psychiatry in our medical schools.

COMMITTEE ON PREVENTIVE PSYCHIATRY—*Chairman*, Lloyd J. Thompson: This committee has continued to focus its major working effort on preventive mental hygiene at various stages of life, preparing a comprehensive bibliography of material available from many sources dealing with the periods of infancy, pre-natal life, natal life, neo-natal life, infancy and pre-school years. It is the hope that such material might prove helpful to workers in all fields of health as well as to educators, clergy, lawyers and others. The committee conducted a roundtable at the annual meeting on the parent-child relationships during the pre-school years.

COMMITTEE ON PUBLIC INFORMATION—*Chairman*, Dr. Robert Morse: After 5 years of work the committee has completed and published a psychiatric glossary, 20,000 of which have already been sold. The booklet on "Psychiatry, the Press and the Public" has sold over 6,000 copies. The committee assisted in drafting two widely publicized releases this year, one on tranquilizing drugs and the other on drug addiction. The com-

mittee has given much time and thought with an organization known as "official films" which represents Mr. Paddy Chayefsky, to the development of a pilot TV program to be offered to commercial sponsors. An increasing number of manuscripts from science writers have been received by the committee with a request for editorial review during the past year. Commendations in increasing number have been received by the Association for the method of handling our press relationships at the annual meeting. It is expected that upwards of 100 reporters will attend this year's meeting.

COMMITTEE ON VETERANS—*Chairman*, David J. Flicker: This committee's assignment is to improve the lot of the mentally disabled veteran as well as to improve the status of our members who are engaged in caring for these patients. They have focused on the improvement of the salary scale for physicians in the Veterans Administration. They have undertaken to change the pattern of the budgetary allotments of the VA so that consideration will be given to those hospitals that have an active turnover picture instead of just a large daily patient load. The committee sponsored a roundtable at the annual meeting on the subject of "The VA and Medical Education—A deteriorating relationship?" The committee continues to keep contact with the major veterans organizations as well as an awareness of the pending legislation so that American psychiatry may have a hearing where this is indicated.

As the retiring chairman of this coordinating committee, I again want to commend to the membership of this Association the earnestness, thoughtfulness and hard work that our committees are giving to their assigned task in behalf of American psychiatry.

WILLIAM C. MENNINGER, M. D.,
Chairman.

REPORT OF COORDINATING COMMITTEE ON PROFESSIONAL STANDARDS

The Committee on Relations with Psychology: This Committee continues to work actively with the corresponding committee of the American Psychological Association. It

is watching closely all legislation in this field. It has run into a problem of interpretation of certification as against licensure and is seeking clarification of this point through

legal opinion so that all District Branches and constituent groups of the American Psychiatric Association may have a sound legal basis for a stand in one direction or the other. As this opinion is obtained, it will be circulated to the membership.

The Committee on Nomenclature and Statistics: This Committee has prepared a practical coding system for the gathering of data and use of statistics in psychiatric facilities and is currently trying it out. It is expected that these studies will lead eventually to the publication of a manual. The Committee has found it necessary to define certain common terms and may plan to survey with an interested research group what laymen usually mean by some of these terms. For example, the Committee has prepared a tentative definition of psychotherapy.

The Committee on Standards and Policies of Hospitals and Clinics: This Committee has held several meetings in New York and Chicago as well as the regular meeting in Washington. The Committee has participated in the development of a conference on a national level on volunteers in mental hospitals. This conference will be held in Chicago during June, 1958. Preparatory commissions have been formed and will hold their initial meetings in the immediate future. Certain general changes have been suggested regarding the standards and policies of public hospitals in cooperation with the Central Inspection Board and will later be submitted to Council. Also a revision of standards for chaplains in public psychiatric hospitals has been submitted to the *ad hoc* Committee on Religion and Psychiatry. Finally, an introductory statement on standards for public psychiatric out-patient clinics will be submitted to Council and as approved or amended, will serve as a basis for the writing of standards and policies for such clinics.

The Committee on Psychiatric Social Work: This Committee has dealt with a tentative draft of Standards for Clinical Social Workers distributed by the United States Civil Service Commission. This was an unsatisfactory document. Final action on it was successfully deferred through efforts of your Social Work Committee. The second portion of this draft was studied and

approved. In addition, the Committee is working quite closely with groups of psychiatric social workers and continues to study collaboratively the relationships between psychiatry and psychiatric social work. A Round Table on the "integrated role of the social worker in medical teaching" was presented at the 1957 annual meeting.

The Committee on Legal Aspects of Psychiatry: This Committee has obtained, without cost to the Association, the services of a well-qualified and interested attorney. The Committee is working on the preparation of a model uniform law dealing with the question of privilege. A proposed law has been prepared and this is now to be coordinated with the Committee on Legal Aspects of Psychiatry of the American Bar Association. After agreement is reached, the draft will be presented to Council for approval. In addition, the Committee is working on the problems of including abduction, false arrest, false imprisonment, etc. in malpractice insurance laws, and hopes to resolve this problem. Your Committee was represented in Vermont in a special panel discussion which resulted in the introduction in the Vermont Legislature of a bill to abolish the M'Naghton rule.

The Committee on Private Practice: This Committee conducted a Round Table at the annual meeting on health insurance plans, which it is hoped will result in a report suitable for publication in the Journal. The Committee has been invited to sit with Blue Cross and with the Health Insurance Institute to try to work out some of the problems of definition and description in relation to hospitalization of the mentally ill. The Committee is working also on the problem of fees charged by psychiatrists to doctors and their dependents. The American Psychoanalytic Association had made a survey of its members. The Committee on Private Practice is carrying out a similar survey of the members of the American Psychiatric Association. This will be done to start with by use of a questionnaire.

The Committee on Psychiatric Nursing: This Committee has continued to work on the numerous problems in this field in collaboration with the several nursing organizations. The National League for Nursing

has prepared a proposal for psychiatric aide teacher-training and the Council of the A.P.A. has authorized joint sponsorship of this program with no expense to the Association. Your Committee is still working with the National League on the details of this program and in attempting to raise funds to carry it out.

All of the Committees in this group have continued to work hard and long on the many problems referred to them by Council,

by the Executive Committee, or inherent in their original mission. As Chairman of the Coordinating Committee, I should like to express my gratitude to the chairmen and members of the several Committees and to Council and the Executive Committee for their cooperation, as well as to the members of the staff of the several offices of the APA.

WILFRED BLOOMBERG, M. D.,
Chairman.

"WHILE HUMAN NATURE REMAINS THE SAME"

Many and grievous were the things which befell cities in those revolutionary struggles [between Greek city-states leading to the Peloponnesian War]—things which occur now and will always recur while human nature remains the same, albeit with more or less violence and in different forms according to the particular turn of events. For in peace and prosperity both cities and private men are better disposed, since they are not under the constraint of necessity. But war is a violent schoolmaster: it robs men of their day-to-day margin of sufficiency and debases the character of most to the level of circumstances.

—THUCYDIDES

UTOPIA

In the Twentieth Century war will be dead, the scaffold will be dead, hatred will be dead, frontier boundaries will be dead, dogmas will be dead; man will live. He will possess something higher than all these—a great country, the whole earth, and a great hope, the whole heaven.

—VICTOR HUGO

UTOPIA

Science can, if it chooses, enable our grandchildren to live the good life, by giving them knowledge, self-control, and characters productive of harmony rather than strife. At present it is teaching our children to kill each other, because many men of science are willing to sacrifice the future of mankind to their own momentary prosperity. But this phase will pass when men have acquired the same domination over their own passions that they already have over physical forces of the external world. Then at last we shall have won our freedom.

—BERTRAND RUSSELL
(What I Believe, 1925)

NEWS AND NOTES

NEW YORK CITY COMMUNITY MENTAL HEALTH BOARD.—Dr. Maurice H. Greenhill was inducted on May 27, 1957 by Mayor Robert F. Wagner, as executive director of the N. Y. City Community Mental Health Board. He succeeds Dr. Paul V. Lemkau, who returned to his post as professor of public health at Johns Hopkins University.

A consultant to the surgeon-general of the Army since 1948, Dr. Greenhill is also chief consultant in psychosomatic medicine at Walter Reed General Hospital, a consultant to the VA, and special consultant to the surgeon-general of the U.S. Public Health Service in community service and research. He is the author of the revised commitment laws of North Carolina.

The N. Y. City Community Mental Health Board is a city agency which plans, finances, and coordinates mental health services of public and voluntary agencies. Its budget for the coming year will be over 19 million dollars.

Members of the Board are: Joseph W. McGovern, acting chairman; Grace Abbate, M. D., Leona Baumgartner, M. D., Sol W. Ginsburg, M. D., Frank E. Karselen, Henry L. McCarthy, Mrs. Alice W. Fordyce, and George Kent Weldon.

PSYCHIATRIC REHABILITATION INSTITUTE, DUKE UNIVERSITY.—A 5-day Regional Institute on Psychiatric Rehabilitation was held June 10, 1957, at Duke University, Durham, N. C. This pilot institute was conducted by the Duke University School of Medicine under the auspices of the Department of Health, Education and Welfare, U.S. Public Health Service. Twenty-seven counselors in the Vocational Rehabilitation Departments of 8 states and Puerto Rico were in attendance. Instructors included the psychiatric faculty of Duke University, industrial physicians and personnel, social service and VA officers.

This Institute on Psychiatric Rehabilitation was the first of its kind in the Southeast.

MEDICAL ASSOCIATION OF SOUTH AFRICA.—The 20th annual scientific meeting and the 41st Medical Congress of the Medical Association of South Africa will be held in Durban, Natal, Sept. 16-21, 1957. The headquarters of Congress will be at Red Cross House, Old Fort Road, Durban. There will be 4 plenary sessions as follows:

1. Cerebral Vascular Disease and the Problem of Ageing. Speakers: Sir Russell Brain, President of the Royal College of Physicians of London; Dr. M. M. Suzman, Johannesburg; Dr. F. H. Kooy, Cape Town; Keith L. Allen, Johannesburg; and Prof. E. L. Bortz, Philadelphia.

2. The Parasitic Diseases of Man in Africa. Speakers: Dr. Michael Gelfand, Salisbury, S. Rhodesia; Charles Marks, Salisbury, S. Rhodesia; and Dr. R. Elsdon-Dew, Durban.

3. The Surgery of Repair. Speakers: Sir Harry Platt, President of the Royal College of Surgeons, England; William Gissane, Birmingham; and Prof. T. Pomfret Kilner, Oxford.

4. Recent Advances in Child Care. Speakers: Prof. Alan Moncrieff, London; Dr. D. M. T. Gairdner, Cambridge; and Dr. H. L. Wallace, Durban.

In addition to these plenary sessions there will be numerous scientific sectional meetings in all the recognized specialties. At one of these meetings Prof. V. Kinross-Wright of the department of psychiatry, Baylor University, Houston, Tex., will speak on "New Horizons in Chemotherapy."

INSTITUTE OF PSYCHIATRIC TREATMENT, PHILADELPHIA, PA.—The 5th annual Institute of Psychiatric Treatment will be held in Philadelphia, Pa., October 17, 18, and 19, 1957. For further information write: Dr. Leo Alexander, Chairman, 433 Marlborough St., Boston 15, Mass.

SCHOLARSHIPS FOR TEACHERS OF BLIND CHILDREN.—For the first time in its history, the South will establish its own year-

round program for training teachers of blind children. Five \$1500 scholarships are available for qualified teachers who wish to take this special training, sponsored by the American Foundation for the Blind, the Southern Regional Education Board, and George Peabody College for Teachers, Nashville, Tenn. The American Foundation will support the regional program financially for the first 3 years, and is contributing over \$50,000 for scholarships and a professorship.

Applicants for these scholarships should write to Dr. Lloyd M. Dunn, coordinator of special education, George Peabody College for Teachers, Nashville 5, Tenn., where the training will be given.

ADMINISTRATIVE APPOINTMENTS, N. Y. STATE DEPARTMENT OF MENTAL HYGIENE.—Four major administrative appointments in the N. Y. State service became effective July 1, 1957, as announced by Commissioner Paul H. Hoch.

Dr. Arthur G. Rodgers, director of Binghamton State Hospital, became director of Syracuse State School; Dr. Ulysses Schutzer, assistant director of Central Islip State Hospital, succeeded him as director of Binghamton. Dr. Charles Greenberg, director of Craig Colony, was appointed senior director of Rome State School and Dr. William C. Johnston, former assistant director of Matteawan State Hospital, succeeded him as director of Craig Colony.

ADOLF MEYER MEMORIAL AWARDS.—Dr. D. Ewen Cameron and Dr. A. E. Moll, Allan Memorial Institute, were selected as recipients of the 1957 Adolf Meyer Memorial Awards bestowed for meritorious contributions on behalf of improved care and treatment of the mentally ill, inside and outside of institutions. The award is made by the Association for Improvement of Mental Health.

NORTH SHORE HOSPITAL LECTURE SERIES.—Dr. Samuel Liebman, medical director of the North Shore Hospital, announces that the topic of the Eighth Annual Lecture Series for 1957-58 will be, "Emotional Problems of Childhood." The lectures will be given on the first Wednesday

of every month from October 1957 through June 1958 (2nd Wednesday in January) at the hospital, 225 Sheridan Road, Winnetka, Ill., at 8:00 P. M.

The American Academy of General Practice has approved attendance at this program as meeting their standards for graduate training.

The entire lecture series will be published in 1958 by J. B. Lippincott Co., Philadelphia. Each of the authors and the Board of Directors of the North Shore Hospital have assigned all royalties that will accrue from the sale of this book to The American Psychiatric Association.

HONORS FOR DR. KANNER.—It is a pleasure to note that the Royal Medico-Psychological Association of Great Britain has invited Dr. Leo Kanner, chief of the Children's Psychiatric Service, Johns Hopkins Hospital, to deliver the annual Maudsley Lecture in London, England, November, 1958. Dr. Kanner will be the third psychiatrist from the West and the first child psychiatrist to be so honored. The others were Dr. Charles K. Clarke of the University of Toronto, and Dr. Adolf Meyer of Johns Hopkins University.

Further, Dr. Kanner's services to the Johns Hopkins School of Medicine have been recognized by his appointment as professor of child psychiatry. This represents the first professorship in child psychiatry to be established at the Johns Hopkins University.

ILLINOIS PSYCHIATRIC SOCIETY.—In May 1957, the following members of the Illinois Psychiatric Society were elected to office for the year 1957-58: president, Dr. Kalman Gyarfás, Chicago, Ill.; vice-president, Dr. Nathaniel S. Apter, Chicago, Ill.; secretary treasurer, Dr. Alberto de la Torre, Chicago, Ill.; councilors: Drs. Hugh Carmichael and V. C. Urse, Chicago, Ill.; delegate to assembly of district branches of The American Psychiatric Association: Dr. John R. Adams, Chicago, Ill.; alternate delegate: Dr. Isadore Spinks, Chicago, Ill.

DELAWARE PSYCHIATRIC SOCIETY.—At the recent meeting of the Society, the following officers were elected for the year

1957-58: president, Dr. George DeCherney; vice-president, Dr. James Flaherty; secretary-treasurer, Dr. Walter Davis; councilors: Drs. Charles Katz and Sanford Rogg.

AMERICAN SOCIETY FOR PUBLIC ADMINISTRATION.—At the annual dinner at Albany, N. Y., of the Capital District Chapter of the Society, May 1957, Mrs. Marie Yegella, a teacher at Wassaic State School, won recognition for her pioneering work with severely retarded children when she received the Governor Charles E. Hughes Award in Public Administration. The award is given for significant achievements in public administration which are of outstanding value and usually represent efforts "beyond the call of duty." Mrs. Yegella, working with children with serious physical disabilities, as well as severe mental defects and I.Q.'s under 50, has developed techniques and goals which are now accepted and taught generally.

The Governor Alfred E. Smith award for achievement in a staff position was made at the same time to Dr. Robert F. Korn, assistant commissioner for program development of the Health Department.

PSYCHIATRY IN NEW ZEALAND.—A vigorous program in psychiatry has been instituted at the University of Otago Medical School under the supervision of Dr. Wallace Ironside, senior lecturer. A course of optional lectures in medical psychology is given to 3rd year students, together with clinical tutorials in connection with the department of psychiatry at Dunedin Hospital, of which Dr. Ironside is the senior psychiatrist. The department maintains a senior and junior psychiatrist, a psychologist, psychiatric social worker and a child psychologist.

Emphasis is also placed on child guidance, with conferences held once a fortnight to which are invited those who have to deal with child patients in other fields.

NEW JERSEY NEURO-PSYCHIATRIC INSTITUTE.—The fifth annual psychiatric institute will be held at the New Jersey Neuro-Psychiatric Institute, Princeton, N. J., on Sept. 18, 1957. The general topic for discussion is: Disciplines in Modern Psychiatric Treatment.

Among the participants are: William Malamud, Harry Solomon, Franz Alexander, Robert A. Matthews, Richard Sweigert and Benjamin Simon.

SOUTHERN MENTAL HEALTH COUNCIL.—The Southern Regional Council on Mental Health Training and Research met in Louisville, Ky., June 28-29 to consider several proposed projects and elect officers for the coming year.

The Council, which consists of one member from each of the 16 participating states appointed by its governor plus 8 members appointed by the SREB, was established by the Southern Governors Conference of 1954 after a year-long regional study by the Southern Regional Board of the problems states face in dealing with mental illness and health.

Projects considered at its Louisville meeting included: a proposed experiment in the education of the mentally retarded; exchanges of personnel among mental hospitals for in-service education; and a study on the economic value to states of providing adequate mental care.

A.C.L.S. AID TO THE HUMANITIES.—The American Council of Learned Societies has announced their three-fold program to further humanistic studies. Beginning with the academic year 1958-59, \$300,000 will be made available in three classifications: 1. Fellowship grants to provide opportunities for younger scholars to complete research projects in the humanities or to extend their competences by extensive study. 2. Grants-in-aid, for significant humanistic research in progress. Candidates for these 2 classifications must hold a doctorate or its equivalent in the field of the humanities and be normally under 45 years of age. 3. Special awards for the completion of distinguished works in the humanities by mature scholars nominated by academic or other professional societies.

The humanistic area of learning is interpreted in general as including the following: philosophy, including the philosophy of science and the philosophy of law; philology, language, literature, and linguistics; archae-

ology, art history and musicology (but not applied art or music); history, including the history of science and the history of religions; and cultural anthropology, including folklore. Programs in the social sciences and the natural sciences which have a humanistic emphasis will also be considered.

Completed applications must be received before Sept. 15, 1957, January 15, and March 15, 1958 for Grant-in-aids and before October 15, 1957 for Fellowship Grants. Address: ACLS Grants Program (or ACLS Fellowship Program), 2101 R St., N. W., Washington 8, D. C.

EUPHEMISM

It is reported that Dr. Thurnam in 1895 proposed that in England the County Pauper Lunatic Asylum should be called The Orthophrenic Institution.

MRS. PACKARD AND HER "REFORM"

The entire annals of the insane in the State of Illinois furnish no greater evidence of cruelty to the insane and their friends than this so-called 'reform,' so zealously promoted by Mrs. Packard. As a matter of fact, more persons were found insane by jury trials . . . than were ever wrongfully committed under the earlier system. The effect on the patient was frequently detrimental, arousing in his mind the idea that the court proceedings were for the purpose of substantiating some charge against him, and when found insane he believed himself innocently condemned.

(*Am. J. Insan.*, 69: 571, 1913)

NURSE EVERYWOMAN

Every woman, or at least almost every woman, in England has, at one time or another of her life, charge of the personal health of somebody, whether child or invalid,—in other words, **every woman is a nurse.** . . .

If, then, every woman must at some time or other of her life, become a nurse, i.e., have charge of somebody's health, how immense and how valuable would be the produce of her united experience if every woman would think how to nurse

Notes on Nursing, 1859

BOOK REVIEWS

PSYCHISCHE HYGIENE. Edited by *Erwin Stransky, M.D., and Ernst Brezina, M.D.* (Wien-Bonn: Wilhelm Maudrich, 1955.)

Nine authors have contributed to this book. Nevertheless, an astonishing degree of homogeneity has been achieved, since the contributions of the various authors are clearly influenced by the thinking and previous publications of Stransky, whose main concepts and psychiatric attitudes permeate the entire book. Already in 1931, Stransky, in collaboration with other authors, has published the first German text on mental hygiene. The aim of mental hygiene, according to Stransky, is on one side the preservation of the healthy part of the population in their state of mental health and, on the other, protection of the endangered and susceptible part of the population, (psychopathic personalities recurrent psychoses, behavior problems in children and adolescents, etc.) from such harmful influences as may aggravate their precarious state. Stransky is quite anxious to stress this twofold nature of his mental hygiene concept, since particularly in America, according to his opinion, the second aspect has been overly stressed, almost to the exclusion of the first aspect. Both aspects, according to Stransky, should be taken care of primarily by physicians who are the only ones who can draw the line between necessary and harmful popularization of medical knowledge.

The various authors give due credit to Clifford Beers and Adolf Meyer, but chiefly build on European and particularly Viennese foundations. In his chapter on the history of mental hygiene, Holzer goes back to the ancient Greek philosophers as well as Hippocrates, Marcus Aurelius, Paracelsus, and then calls attention to the interesting and important work of the Austrian physician, scholar and poet, Freiherr von Feuchtersleben. In 1838, Feuchtersleben published a book *Zur Diätetik der Seele*, in which he stresses the principle of prophylaxis in a similar way as it is now being stressed by Stransky. Nevertheless, the impact of the American mental hygiene movement was needed to make mental hygiene, even in the fatherland of Feuchtersleben, into more than a theoretical concept and an attitude of mind on the side of the physician. In his emphasis on prophylaxis Stransky stresses the importance of reasonable diffusion of information, counselling centers, and social work agencies. Since he attributes a great deal of importance to eugenics he is interested in premarital counselling. Even in mild cases of cyclic endogenous depressions he warns against marriage, stressing the hereditary and eugenic factor to a greater extent than is customarily done. The same rather rigid view is extended to patients with convulsive disorders, and one is surprised that in connection with epilepsy, heredity and marriage, the importance of the electroencephalo-

gram is not even mentioned. In major neuroses too, due to emphasis on the constitutional factor, eugenic prophylaxis is being stressed, but it is strongly emphasized that human rights and human dignity should not be encroached upon. Stransky is therefore opposed to legislative measures in this connection. The constitutional, hereditary point of view permeates the entire book. In therapy Stransky stresses his "subordination authority relation." He considers Freudian concepts chiefly as products of phantasy.

Other collaborators are not as radical in their rejection of Freud, and Poetzl who has written an introduction to the book, while recognizing the importance of Stransky's "subordination authority relation," feels constrained to state that he, Poetzl, considers Freud's work as empirically proven. While Stransky does not agree with Poetzl in this respect, he also rejects Pavlov and Speransky's reflexological orientation. In his condemnation of Freud he is particularly extreme: "I would like to say that concerning this specific kind of psychopathization of our present society with all its consequences, the Freudian movement is not entirely guiltless. This movement and its derivatives in the English speaking world have given rise to a kind of slogan used by millions of laymen . . . nothing is more harmful than an undigested half-knowledge, particularly a half-knowledge which accepts theses as little founded as those of Freud and Adler as given facts."

A more moderate, thoroughly eclectic and thoroughly mature view concerning psychotherapy and its methods is presented in the chapter on 'psychotherapy and mental hygiene' by Hans Kogerer. While he denies the particular therapeutic efficacy of psychoanalysis his thinking is deeply influenced by Freud. He accepts Freud's findings concerning infantile sexuality, the importance of instincts and drives, but argues against the partition into conscious and unconscious and "its personification as ego and id." This as well as the concept of the ideal ego and super-ego Kogerer considers as metaphysical constructions of the antimetaphysician Freud. The antithesis of pleasure and reality principle he views in a similar light as a metaphysical construction. Next to Freud, Kogerer has been influenced most by Kretschmer, Jung, Adler, Frankl and Kronfeld. In the reviewer's opinion he has succeeded in integrating effectively the fundamentals of these various schools of psychotherapy. His chapter may be of particular interest to the general American psychiatric reader who is well acquainted with the Freudian but not with the other psychotherapeutic approaches.

In his chapter on 'mental hygiene and crime,' Stransky again stresses the hereditary constitutional point of view and states that in America the importance of the milieu has been overrated, although

he, himself, does not deny it. He feels that American pedagogics are too permissive and in this connection too stresses the "subordination authority relation" approach.

In other chapters the relationship of mental hygiene to physical hygiene, sociology and economics are being discussed. One is somewhat surprised to see which progressive steps in Austria, or at least in Vienna, have been taken. There is, for instance, routine mental hygiene counselling at the end of Highschool for healthy students (emphasis on prophylaxis). In Vienna there are special counselling centers for suicidal risks (Beratungsstellen fuer Lebensmuede).

The entire book is on a high level and reflects the European point of view on mental hygiene. That this point of view in many aspects is considerably different from ours makes the book particularly interesting and worthwhile reading. While one may not agree with all conclusions one can not fail to be impressed by the originality of many of the proposed points of view and by the thoroughness with which the entire field has been covered.

CRESTWOOD HEIGHTS: A STUDY OF THE CULTURE OF SUBURBAN LIFE. By John R. Seeley, R. Alexander Sim, and Elisabeth W. Loosley. (New York: Basic Books; and Toronto: Univ. of Toronto Press, 1956. \$6.50.)

This book describes many aspects of life in Suburbia—a particular Suburbia, to be sure—but with features common to suburban (and in many ways urban uppermiddle class) society throughout North America. It is an important book for psychiatrists whose private clientele is drawn largely from this section of the population. In addition it has much to say that is relevant to the psychiatrists themselves, both as members of this social stratum and also as practitioners.

Since few psychiatrists, in all likelihood, will want to tackle such a thick book on a subject that may seem tangential to their main concerns, I would recommend that as many as possible read with care Part 3: Integration, and Part 4: Implication. Part 3 summarizes and sorts out the material of the preceding 300-plus pages. Part 4 raises problems that mental health experts of all kinds must face but that many of us are scarcely aware of.

These 2 sections are related to the rest of the book in the same way that a summary at a psychiatric case conference is related to the life history and details of clinical contacts with the patient. They are, in addition, very stimulating reading, particularly as they deal with the role and functioning of our professional fraternity. The views expressed may engender strong reactions for and against; they should certainly stir us into a greater awareness of our potentials and responsibilities to society.

JUDAISM AND PSYCHIATRY. Edited by Simon Noveck. (New York: The National Academy for Adult Jewish Studies, 1956. \$2.50.)

This book is another welcome indicator of the rising tide of interest in religion and psychiatry. Five well known Rabbis and 10 competent psychiatrists have joined forces to provide us with a most useful and enlightening volume. Almost all of the papers were originally presented as informal talks to adult education classes of the Park Avenue Synagogue, and now appear under the skillful editorship of Rabbi Noveck in highly readable form. The purpose of the book as stated by the editor is "to present some of the teachings of the Jewish tradition on the basic emotional problems which confront us as human beings, and to analyze the psychological values which can come from following the Jewish way of life." To accomplish this the subjects of Conscience and Guilt, Fear and Anxiety, Depression, and Self-Acceptance are discussed from both the psychiatric and Jewish points of view. There are also excellent discussions on The Meaning of Personal Religious Experience, The Value of Ritual, and The Need to Belong, to mention only a few of the chapter headings. The final section is devoted to 3 statements (by one Rabbi and two psychiatrists) addressed to the question: "Can Judaism and psychiatry meet?"

Although the answer to the above question is in the affirmative, there remains for the authors a keen recognition of the essentially different and separate areas of the 2 fields, even though they may appear to overlap or demonstrate, at times, a superficial similarity. This is but one example of the spirit of common sense and intelligent appraisal which runs through the entire book.

Both Jew and non-Jew will enjoy the many pertinent quotations and examples from the Old Testament, Talmud, and other Jewish writings. There is an excellent bibliography which omits, for some inexplicable reason, any reference to Martin Buber, the great contemporary Jewish theologian who has contributed so importantly to this very subject. This book can be safely recommended to any person, lay or professional, who wishes to understand some of the fundamental precepts of the Jewish faith, and how they relate to the emotional problems of everyday living.

Washington, D.C.

HOW TO IMPROVE YOUR MIND. By Baruch Spinoza, with Biographical Notes by Danabert D. Runes. (New York: Wisdom Library (Philosophical Library) 1956. \$95. Soft Binding.)

This 90 page text is a translation from the Latin *De Intellectus Emendatione*, by R. H. M. Elwes. From the mid-twentieth century standpoint the title is deceptive. The book is not a psychiatric self-help poster of the type with which we are all too familiar. The contemporary social climate is rather curious, probably different from anything before experienced. An unfortunate side effect of the real of our fraternity to educate the public is to make

many a sensitive brother or sister morbidly mind-conscious. Such persons function better and more comfortably as little aware as possible of their physiology, whether of mind or body. But we do not allow them to be unaware. Through a flood of books and other means of communication we spread before them an assortment of nervous symptoms they are liable to; then if the inoculation "takes," it is of course necessary to write more books full of antidotes. We increase the demand and then the supply.

Spinoza's text is not that kind of book. Spinoza is a philosopher and he writes like one, with frequent references to his profounder and more detailed books. His method is what he calls pure reason by which the relativeness of qualities is appreciated. Thus in nature nothing is that must be either one thing or the other, *i.e.*, either good or bad. It becomes such only in relation to the self. One must therefore strive to know as much about nature, all of nature, as possible, thus acquiring knowledge of God, for God and nature are one and

the same. Man thus attains to an *amor dei intellectualis* free of all emotional involvement.

Spinoza, the philosopher, using the language of his *metier*, addresses himself in as simple terms as possible to those, nevertheless, who are able to assimilate his canons of logical thinking. Obviously he is not speaking to those not so endowed; and, like Kant, he assumes the existence of this something called "pure reason."

He found that the goals that the multitude commonly seeks are riches, fame, and pleasures of the senses; and he apprehended these as unworthy and unsatisfactory goals; he must find something beyond and above all these, nothing less indeed than "the knowledge of the union existing between the mind and the whole of nature." Attaining such knowledge he must help others to attain it also. That was his purpose in writing this book, and its value lies in letting us look in upon the mind of this great man at work. He was only 26 years old when he wrote it.

NEW GERMAN PSYCHIATRICA AND PSYCHOLOGICA

HANS A. ILLING, LOS ANGELES, CAL.

TIEFENPSYCHOLOGIE. DEPTH-PSYCHOLOGY. By *Friedrich Seifert*. (Dusseldorf and Koeln: Eugen Diederichs Verlag, 1955. DM 15.80.)

Tiefenpsychologie is a postwar coinage in the German-speaking countries. Among the best of a flood of new titles is this one with the subtitle, *Die Entwicklung der Lehre vom Unbewussten*. Significantly for American readers, Seifert divides the science into a "magnetic field" of the theories of Freud and Adler in one part and a "magnetic field of ideas" of Jung in another, both parts being quite equal in extent. So far as the part on Jung is concerned, this is probably the best integration and interpretation to be found in any domestic or foreign work, even though Seifert seems to incline toward Jung, since in Germany much tiefenpsychologie rests on mythology, alchemy, religion, and parapsychology. In the part on Freud, particularly in the chapter on "Psychoanalytische Nervenlehre," Seifert stresses the origins of Freud's psychoanalysis, including sociological, cultural, historical, and even religious factors, but omits medical factors, an approach hardly shared by most American analysts.

GESATZE UND SINN DES TRAUMENS. By *K. Leonhard*. (Stuttgart: Georg Thieme, 1955. DM 11.70.)

In this more specialized monograph on tiefenpsychologie, medical psychologist Leonhard makes the claim that most psychotherapists in Germany reject Freud's as well as Jung's theories (the former basing his interpretations on dreams on sexual symbols, the latter on collective archetypes) and that "one could agree with one or the other or with neither." (A claim which, in this reviewer's opinion, the author himself inconsistently refutes in

his own "theories," since one would have to "agree" with him.) Interpretation of dreams, in Leonhard's opinion, is to be avoided, since dreams contain "unconscious powers, which complement the achievements of the conscious in harmonious co-operation."

PHANTASIE. By *Karl Heymann*. (Basle: S. Karger, 1956. S.frs. 9.35.)

INFANTILISMUS. (Basle: S. Karger, 1955. S.frs. 20.80.)

The first monograph deals with the phantasy and its various implications for social hygiene, education, the arts, and political science. The author is an educational psychologist, and his book is one of a large series of monographs devoted largely to education and child welfare. The author believes that phantasy is a phenomenon that one has to deal with clinically and as an observer. Only when the researcher picks up the single pieces can he understand the whole idea of the phantasy as an extra- rather than intrapsychic phenomenon in our emotional life.

In the second monograph published by the same author, a number of savants have participated, half of them of the medical-psychiatric discipline. Differing from our American type of research, in Europe it is the medical profession that pioneers in projective tests, particularly the Rorschach (since Rorschach was a psychiatrist), whereas our psychiatrists seem to have a hands off attitude. The infantile individual gets in this volume a thorough treatment and is studied as a soldier, in vocational counseling, with first graders in elementary schools, mental defectives, and delinquents.

WILLE UND LEISTUNG. By *Karl Mierke*. (Goettingen: Verlag fuer Psychologie, Dr. C. J. Hogrefe, 1955. DM 28.60.)

Here an attempt is made on the basis of experiments to arrive at conclusions as to the interrelationships between the methods of experimental psychology and those of psychodiagnostics, as well as between comparative and the *verstehende* (comprehending) psychology. Analyzed and illustrated are a series of concepts of "achievements," such as work and achievement, capacity of achievement, drive for achievement, trend of determination and Gestalt, and a host of others.

MYSTERIUM CONIUNCTIONIS. Vols. I and II. By *C. G. Jung*. (Zurich: Rascher Verlag, 1955, S.frs. 12; and 1956, S.frs. 16.)

Jung's latest opus appears in two volumes, the third and final one having been announced for early 1957. The first volume contains Chapters I through III, the second volume Chapters IV through VI. Jung's theory of the archetypes seems to have been worked out to the finest detail and is based on the alchemists' many-sided symbols. For instance, Chapter V deals with Adam and Eve, the various sources of biblical and scholarly origins, such as the Kabbala, interpretation of names, etc. For the student of Jung these three volumes will probably constitute the Master's swan-song and be an absolute "Must"; for the researcher, however, they will mark the zenith of philological scholarship.

ERFAHRUNGEN MIT GRUPPENPSYCHOTHERAPIE. By *Adolf Guggenbuehl-Craig*. (Basle: S. Karger, 1956. S.fr. 8.—.)

The author gives his readers a report of his visit to, and internship in, the Nebraska Psychiatric Institute, where he observed, studied, and practiced group psychotherapy in 1955. This little monograph is one of the best of its kind and demonstrates how much can be stated in a small space and yet avoid the pitfall of oversimplification. To be sure, much material, historical, clinical, methodological, is missing. But the brief bibliography, consisting of 31 references, all Anglo-Saxon material, contains perhaps the essence of group-therapy literature.

KRITIK DER PSYCHOSOMATIK. By *Hans Joerg Weitbrecht*. (Stuttgart: Georg Thieme, 1955. DM 12.)

DIE KRANKHEIT NICHT KRANK SEIN ZU KOENNEN. By *Hans Mueller-Eckhard*. (Stuttgart: Ernst Klett Verlag, 1955. DM 12.)

These two major publications emphasize the polarity of opinion in German-speaking countries today concerning psychosomatics. Strangely enough, it is the medical writer Weitbrecht who appears to be opposed to "those analysts and psychiatrists" who strive toward therapeutic and who modify Freud's theory of the neuroses into a "universal anthropology." He quotes particularly Franz Alexander as one of the principal pro-

tagonists of how "psychosomatics may be applied to every phenomenon which exists within the living organism." This, the author feels, is a "materialistic monism," which is the antithesis of the "idealistic spiritualism" mainly represented by the German psychosomatic practitioners.

In contrast to Weitbrecht, Mueller-Eckhard advocates not only spirituality, which he feels psychiatrists, including the German, do not have, but also a movement back from the physio-chemical point of view of "neuropsychiatry," and the push-button treatment of a patient who needs more than that. In fact, he claims that it is the psychiatrists who have contributed to, and have increased, the incidence of mental illness, at least in German-speaking countries. In many instances, as in shock therapy, the author has found confirmation in many medical sources both in Germany and in this country. At the same time, his book, one of the best-written in psychiatry, cannot escape oversimplification and general statements which are simply not correct. Nevertheless, reports which have reached this reviewer indicate that this book, published less than a year ago, has already sold more than 100,000 copies, is advertised in medical journals (outside of neurology and psychiatry) and seems to have done tremendous damage, thanks to psychiatrists themselves.

PSYCHOGENE ERKRANKUNGEN BEI KINDERN UND JUGENGLICHEN. By *Annemarie Duehrssen*. (Goettingen: Verlag fuer Medizinische Psychologie, 1955. DM 18.)

The author, co-editor of the *Zeitschrift fuer Psycho-Somatische Medizin*, and a child psychiatrist, writes in a neo-analytical fashion, being a student of Harald Schultz-Hencke. However, she wishes the reader to know that Freud's theory on childhood neuroses, whether psychosomatically conditioned or not, was developed further by Adler and Kuenkel. She speaks as a medical psychologist and wishes to avoid "interdisciplinary difficulties" in writing her text, even though she seems to be aware that there may be more nonmedical than medical practitioners of various disciplines engaged in child psychology. There are few books like hers that blend harmoniously the physiological and psychological aspects of child development from infancy to adolescence.

KINDERPSYCHOTHERAPIE IN NICHT-DIREKTIVEM VERFAHREN. By *Reinhard and Anne-Marie Tausch*. (Goettingen: Verlag fuer Psychologie, Dr. C. J. Hogrefe, 1956. DM 8.60.)

This book by two educational psychologists is unique in German literature, insofar as it is probably the first dealing with Rogerian nondirective psychology, translated into German phraseology, methodology, and setting. The volume is based almost entirely on Rogers and Axline; it is listed here because of its uniqueness and novelty, since American readers can be considered as largely familiar with this school of psychology.

THE EVALUATION OF THE EFFECTS OF DERIVATIVES OF RAUWOLFIA IN THE TREATMENT OF SCHIZOPHRENIA¹

WILLIAM MALAMUD, M.D., WALTER E. BARTON, M.D., ALICE M. FLEMING, M.D.,
PETER McK. MIDDLETON, M.D., TOBIAS T. FRIEDMAN, M.D., AND
MAXWELL J. SCHLEIFER, PH.D.²

In this communication we wish to present the results of a study, the purpose of which was to evaluate certain aspects of the effects of a number of derivatives of Rauwolfia in the treatment of patients suffering from schizophrenia. Shortly after the introduction of the use of Rauwolfia or some of its derivatives in the treatment of hypertension, it was noted that they also exerted a beneficial effect upon certain psychopathological symptoms, notably anxiety, tension, worry and irritability, and have come to be popularly known as "tranquillizing" drugs. Since then, these substances along with others which were found to produce more or less similar effects, have been widely used in the treatment of personality disturbances and a considerable amount of literature has accumulated on this subject. Whereas it is generally agreed that beneficial results can be obtained with the use of these drugs, a number of questions have not been satisfactorily answered, and in regard to other questions there is considerable lack of agreement. The particular questions which appear to us to have been left in doubt are the following: What are the relative therapeutic merits of each one of the specific derivatives of Rauwolfia as compared with one another? How do these effects compare with an adequately controlled use of placebos? How well are the beneficial effects, if any, maintained after the termination of treatment? Are there any specific psychopathological phenomena that are especially likely to be beneficially affected by any or all of these drugs regardless of the general effect in a given disease entity?

The present study was undertaken to try to answer these questions. Six derivatives

of Rauwolfia were selected for study, each one being designated by its generic name, with the trade name in parentheses. The actual names of these drugs, as well as the placebos, were not known to those who administered the medication and recorded the observations, the various substances being designated by letters of the alphabet, and it was only after the completion of the study that the code letter was translated into the appropriate name of the substance.

All drugs and placebos, regardless of actual dose, were administered in a uniform manner as follows: 2-cc. ampules by intramuscular injection for 21 days, followed by 3 small tablets daily for the rest of the period (total period of treatment 12 weeks). Another group received orally 3 large tablets daily for 21 days, followed by 3 small tablets daily for the rest of the 12-week period. We did not find any appreciable difference in the effects of each drug whether administered intramuscularly or orally, and in our final evaluation of the effects, we have combined the results of the two methods of administration. Two of the drugs, viz. Rauwiloid and Serpalkon, were administered only orally to one group each. The following is a list of the drugs used, with a brief statement concerning their nature and their general physiological and pharmacological effects.³

1. *Alseroxylon* (Rauwiloid), designated by letter G. This is a selected fraction of the Rauwolfia alkaloids from which the sympatholytic and hypertensive alkaloids have been removed. It represents the total anti-hypertensive, bradycardic and sedative activities of Rauwolfia *Serpentina*. Dosage: Large tablets containing 20 mg. each and

¹ Read at the 113th annual meeting of The American Psychiatric Association, Chicago, Ill., May 13-17, 1957.

² From the Division of Psychiatry, Boston University School of Medicine, and the Clinical Service of the Boston State Hospital, Boston, Mass.

³ All of these substances, including placebos, were furnished by the Riker Laboratories, Inc. For this material and for some financial help, as well as valuable advice and suggestions in the setting up of this study, we are indebted to the Riker Laboratories.

small tablets containing 6 mg. each. Number of patients—15.

2. *Reserpine* (Serpiloid), designated by letter C. This is one of the pharmacologically active alkaloids obtained from *Rauwolfia*. It manifests sedative, bradycardic and anti-hypertensive actions, apparently manifested through the hypothalamus. It tends to have depressive sequelae. Dosage: Ampules 5 mg. per cc.; large tablets 3.3 mg. each; small tablets 1 mg. each. Number of patients—33.

3. *Rescinnamine* (Rescamine), designated by letter A. This is another alkaloid of *Rauwolfia* which manifests anti-hypertensive and bradycardic action. It differs from reserpine in that it is less prone to produce excessive sedation. Dosage: Ampules 5 mg. per cc.; large tablets 3.3 mg. each; small tablets 1 mg. each. Number of patients—31.

4. *Deserpidine* (Recanescine), designated by letter B. This is still another pharmacologically active derivative of *Rauwolfia*. It has been shown to produce approximately the same anti-hypertensive and sedative responses as reserpine. Dosage: Ampules 5 mg. per cc.; large tablets 3.3 mg. each; small tablets 1 mg. each. Number of patients—33.

5. A combination of reserpine (60%), rescinnamine (20%), and deserpidine (20%), under the trade name of *Triserpine* and designated by letters E and H. Laboratory data indicate that potentiation results from an administration of the mixed alkaloid in its effects upon hypertension. Dosage: Ampules 5 mg. per cc.; large tablets 3.3 mg. each; small tablets 1 mg. each. Number of patients—29.

6. Another fraction from *Rauwolfia Serpentina* of Indian origin, composed of primarily weak bases but not totally alkaloidal, under the trade name of *Serpalkon*, was designated by letter F. It manifests the typical *Rauwolfia* effects of sedation, bradycardia and hypertension. Dosage: Large tablets 4 mg. each; small tablets 1.2 mg. each. Number of patients—17.

7. Finally, placebos, designated by letter D, and obviously containing none of the above alkaloids. It too was administered in the form of ampules, large and small tablets. Number of patients—34.

All of these substances were administered

in approximately equal numbers of cases orally and by injection. The capsules and ampules were identical in appearance in all cases, and, in order to reduce further the possibility of subjective influences, the same substance was sometimes used under two separate letters to avoid the possibility of influencing the evaluation of the effect of any given one of these substances. It is because of this that we actually had 12 differently designated substances.

PROCEDURE

The patients used were all chronic schizophrenics who had been hospitalized for over 2 years and some of them had been previously treated by other methods, without any appreciable effects. We have selected chronic schizophrenics for the following reasons: in the first place, after a period of observation and study, the diagnosis was less likely to be in doubt; secondly, it is a well known fact that in the acute cases of this disease, almost any form of therapy frequently produces transient or even more prolonged states of remission. This was obviated by the fact that they were chronic patients. Thirdly, in the acute phases of the disease, there is always the justifiable tendency to try a variety of methods of therapy. In the chronic patients, however, it was easier to restrict ourselves to one method only and then wait for results of a follow-up study. Finally, a great deal has been said about the fact that some of these drugs are particularly likely to produce good results in the chronic hospitalized patients, thereby reducing materially the burden of accumulation of a great many chronic cases, and we were especially interested in testing this contention.

Two hundred forty patients, male and female, were selected with the idea of having an initial 20 patients for each of the substances designated by a special letter. The patients were selected out of a large number of cases in the hospital; and an initial psychiatric examination was done in each case, paying particular attention to the duration of the illness and of hospitalization, the history of the onset and course of the disease, its severity and the particular types of disturbances manifested during the course. The

mental status of each patient was recorded before the beginning of treatment. The patients were assigned to each one of these substances with a view to having, as far as possible, a similar distribution of the type of patient and nature of the disease in all of the groups, so that we could subsequently have a more reliable basis for evaluation of the effects of each drug. In order to determine the specific effect of each one of these substances on certain types of psychopathological disturbances, we chose a number of behavioral items which could be readily observed both by the psychiatrist and the ward personnel, and changes in each one of these items was noted by subsequent examinations during the 12 weeks treatment in each case, again shortly after the termination of treatment, and then at the end of a 6-months to one year follow-up period. These behavioral items were as follows: anger, combativeness, noisiness, disturbances in activity (either hyperactivity or retardation), difficulties in cooperation and in communication, autism, untidiness, aloofness, disturbances in affect, disturbances in night rest, and, finally, disturbances in food intake. The status of each one of these behavioral phenomena was recorded in terms of good, fair or poor, before the beginning of treatment. This was essential since in the different patients, regardless of the severity of their illness, some of these items may not have shown any apparent pathology and obviously the final results, if satisfactory, would have to be evaluated against the background of the original status. The evaluation of each item in terms of possible change related to the treatment, was undertaken during the course of the 12 weeks of treatment, a short while after the withdrawal of the drug, and then at the end of the follow-up period. In this way we hoped to be able to obtain some information not only as to the specific effect of a given substance on a special psychopathological phenomenon, but also as to how well this effect can be maintained after the drug has been discontinued. Finally, at the end of the follow-up period, a general evaluation of the condition of the patients as compared with their original status was made by the combined hospital personnel in terms of improvement, as contrasted with either no

change or even a worsening of the condition.

For a number of reasons, some of the 240 patients had to be dropped from the study, and we finished at the end of the follow-up period with 192 patients, 45 males and 147 females. One hundred eighty-three of these patients were diagnosed schizophrenia all through their stay in the hospital. In 9 patients, other diagnoses were made at certain times during their hospitalization, but the condition at the time of the beginning of the treatment was primarily that of a schizophrenic psychosis. In the following chart (Chart 1), we have tabulated the general information concerning these patients in regard to the distribution of age, sex, duration of the illness and of hospitalization, the substances used and the numbers of patients treated by each substance.

During the study, observations were checked when possible by two or more persons so as to exclude personal equations. We also made observations on any side effects, particularly where untoward complications occurred. In only 3 patients of the original group we had to interrupt treatment because of physical complications. In two of these, the administration could be resumed after a period of interruption; in one, however, the treatment had to be discontinued.

RESULTS

The nature of the behavioral items which served as the basis of this evaluation, as indeed the nature of schizophrenia itself, makes it impossible to report results in terms of exact quantitative differences. At best, we can compare changes in each of these behavioral items and in the status of the patient as a total personality in qualitative terms, noting particularly whether a given behavior item or the general status of the patient at any given time was either "good," "fair" or "poor." It was also impossible to assign proper weighting to each one of these items on a quantitative basis. Thus, for instance, we could not say with certainty whether an improvement in an originally pathological state of affect was more or less important than similar changes in autism or disturbed activity. We therefore concen-

CHART 1

Patients	Number 192	Male 45	Female 147
Course of illness	Duration of illness: 2-35 years Median: 14 years	Hospital stay: 14-35 years Median: 12.5 years	
Substances used	Alseroxylon (Rauwolfoid) 15 patients	Reserpine (Serpiloid) 33 patients	Rescinnamine (Rescamine) 31 patients
		Deserpidine (Recauscine) 33 patients	(Triserpine) 29 patients
			(Serpalkon) 17 patients
			Placebo 34 patients

trated entirely upon recording the qualitative changes in a given item as observed in patients treated with one drug as compared with what occurred in a similar item in patients treated by other drugs or placebos. It must also be kept in mind that certain behavioral items may have shown no appreciable degree of disturbance in individual patients, which meant that in comparing the effects of these substances we had to take into consideration not only the condition at any time during the period of observation, but also the original status of that item before treatment was started. The absence of a change in any one of these items either to the better or worse did not necessarily mean that the drug had no effect, but might be dependent on the fact that the condition of that particular behavior function was not pathological in the first place and therefore could not change to the better although it could become worse. Similarly, where the condition was very poor to begin with, the end result could not become any worse although it could change to the better. With these points in mind we wish to report the following results:

1. *Effects of these substances in terms of consistent changes in the various items during the course of treatment.* These results are tabulated in Chart 2. Here we find that combining the effects on all of the items and allowing for the possible movement towards either improvement or worsening of the condition, the various substances, including the placebos, range themselves in a general order of rank with "1" indicating the greatest effect towards improvement and "7" indicating little or no beneficial effect, or even a worsening of the condition. The results indicate 2 bases of comparison:

a. Since in each item the highest beneficial effects are indicated by the lowest numbers, the sum total of the ranks of all 12 items will provide a rank order of the 7 substances used, and in this respect, Triserpine with a total of 29 will rank as the most effective, whereas the placebos with a total of 70.5 will rank seventh or least effective, with the rest arranged in order between these two.

b. The various drugs show tendencies towards specific effects on certain items. Thus, for instance, Triserpine seems to show the

CHART 2

THERAPEUTIC EFFECTS DURING COURSE OF TREATMENT

comparatively highest effect on communication, autism, untidiness, aloofness and affect; whereas rescinnamine shows comparatively high effects on the first 8 of the 12 items. Occasionally we find a drug, as, for instance, deserpidine, which may show very little effect on most of the behavior items, but the highest effect on a specific one (activity). Here too we find that the placebos tend to rank mostly at the bottom of the list. Two things must be remembered in evaluating the results in this particular chart. First, they represent primarily symptomatic effects during the actual administration of the drug and this, obviously, does not indicate so far to what extent these beneficial effects may be maintained after the drug has been discontinued. Secondly, they do not, of necessity, indicate any quantitative weighting of these effects. Thus, in the case of Trisperine, although 4 of the items are ranked 1, therefore indicating that during the treatment this substance has produced the comparatively highest beneficial effect on these particular items, nevertheless there was not quite as much difference between 1 and

7 in this group of items as there was, for instance, in regard to the first 5 items in which rescinnamine seems to have been most effective. The differences here between ranks 1 and 7 were much more distinct and reliable than in the case of the items affected by Triserpine. Actually the items in which Triserpine ranks first, were representative of the basic disturbances of schizophrenia and none of the drugs produced any marked effect on these symptoms.

2. *The maintenance of the effects after the termination of treatment and at the end of the follow-up period.* These results are tabulated in Chart 3. The most striking contrast in this chart is to be observed in the comparison between rescinnamine (Rescamine) which ranks 1st and the placebos which rank 7th. Both are consistent in maintaining the effects produced, but, whereas rescinnamine seems to maintain its highest degree of efficiency throughout the period of study both in regard to specific behavioral items and the general evaluation, the placebos remain throughout the same period with the least beneficial effects. It must be added, however, that this

CHART 3

RANK ORDER OF THERAPEUTIC EFFECTS OF THE DRUGS THROUGHOUT THE PERIOD OF TREATMENT AND FOLLOW-UP

Drug	Course of treatment	Termination of treatment	6-12 months follow-up symptoms	6-12 months follow-up general evaluation
A				
Rescinnamine (Rescamine). 2	2	1	2	
G				
Alseroxylon (Rauwiloid) . 3	4	2	3	
E-H				
Combination of A, B and C (Triserpine) 1	2	3	7	
F				
(Serpalkon) 6	7	4	4	
C				
Reserpine (Serpiloid) 4	1	5	5	
B				
Deserpidine (Rescanscine) 5	5	6	1	
D				
Placebo 7	6	7	6	

difference is only comparative. Actually when we compare the results at the end of the follow-up period, we find that in the patients treated with rescinnamine, 29% were improved and 71% were unchanged or worse, whereas the figures for the placebos were 16% improved and 84% unchanged or worse.

In regard to the evaluation of the other drugs, it is of interest to note that reserpine showed its best effects shortly after termination of the treatment, but failed to maintain these effects by the end of the follow-up period either in regard to effects on specific behavior items (Column 3) or in the general status (Column 4). Furthermore, Triserpine which ranked 1st in effectiveness during the course of treatment, consistently lost ground during the follow-up, and showed particularly poor results in the general evaluation at the end of follow-up. Finally, deserpidine, which was consistently low in its effects on specific behavior items (Columns 1, 2 and 3), was found to have most improvements, as judged by general evaluation, at the end of the follow-up period (31% im-

provements and 69% unchanged or worse). This may be due to the fact that the original beneficial effects of this drug were to reduce the disturbances in activity and assaultiveness and these effects were well maintained. It is easy to see that in a general evaluation of the adjustability of the patient, these two items would be particularly important.

Throughout the study, particular attention was given to the development of side effects of these substances. All the drugs showed such effects and they were, of course, absent only in the patients receiving placebos. These side effects were, generally speaking, quite mild and consisted of drooling, stuffiness of the nose, somnolence, loose stools, restlessness, depression and transitory mild parkinsonian symptoms. These were liberally sprinkled among all the drugs and subsided as the treatment progressed. A few patients who showed more definite parkinsonian symptoms were treated successfully by temporary suspension of the drug and administration of Cogentin 2 mg. t.i.d. Where untoward symptoms failed to subside, treatment was discontinued. There was one fatality in which the official postmortem diagnosis was cardiac decompensation and was not considered by the pathologist as due to the drug. This patient manifested signs of cardiac disease before and it is likely that such a condition should be considered as a contraindication for the use of these drugs. This remains questionable, however, and can only be more positively answered after further observations.

In the present communication we have restricted ourselves to a certain sector of the data relevant to the questions posited in the introduction. Some features such as the significance of the background of the patients studied, the nature and severity of the illness in individual cases, the specificity of side effects in relation to each drug and a number of others require further analysis and we propose to deal with these in future communications.

SUMMARY AND CONCLUSIONS

Six derivatives of Rauwolfia were used in the treatment of a series of chronic schizophrenics, and the therapeutic results were

compared among themselves and with results obtained through the use of placebos. The patients were selected with consideration of adequate matching and were evaluated psychiatrically before treatment. The course of their illness was systematically studied during the administration of the treatment and for a period of 6 months to one year after termination of the treatment. The comparison of the effects of both drugs and placebos was in terms of changes in specific behavior items, as well as the general evaluation of their clinical status and adjustment in the hospital or outside as judged by the hospital personnel. The results obtained justify the following conclusions:

1. The drugs differed from one another in terms of the degree of beneficial effect on the general condition of the patients, some being more effective than others; and all the drugs were more effective than the placebos. However, the spread was not too wide and some improvements were observed even in the patients to whom placebos were administered.

2. The effects of the drugs showed a trend toward specificity in that each drug tended to have a greater effect upon certain behavior items than was obtained with other drugs.

3. In the case of some of the drugs, the beneficial effect produced during treatment was maintained after termination and through the follow-up period, whereas in others this effect was not maintained.

DISCUSSION

WERNER TUTEUR, M. D. (Elgin, Ill.). The term "chronic schizophrenic," in connection with studies on tranquilizing drugs, is frequently misleading. Many a long standing patient in a mental institution has been mislabeled through the years. In our studies at Elgin State Hospital for the past years we have been restricting ourselves to admitting patients to special studies by symptoms rather than by diagnoses. We feel that thus we may at least avoid one source of error, that of diagnosis. This is entirely permissible as long as we have to treat in our field unspecific illnesses with unspecific means.

The double blind method of investigation remains the most reliable at this time, yet the pitfalls of it have been mentioned in the literature (1, 2), and were it not for the fact that scientists invariably give the active compound a bias and that only too frequently there is a watering of the patient's con-

dition on placebos, it might become a valuable tool in psychiatric drug research. Experienced ward personnel may easily demoralize "blinded" investigators by expressing their valuable opinions as to "loaded or blank" medication. Severe warnings regarding this are necessary on the part of the chief investigator at the beginning of each study.

Twelve weeks of treatment with active compounds, experimentally, is gratifyingly long in contrast to many studies where patients are kept on the compounds for a much shorter period.

Quantitative evaluations remain difficult, and it is doubtful whether any of the individual derivatives affect certain symptoms, since the psychiatric symptom remains entirely the patient's personal property and has to be interpreted as such.

The authors mention nothing regarding discharge of any of their patients. If the follow-up study was performed while patients remained in the institution, then due allowance has to be given to the protecting institutional environment which continued after the patients had been taken off medication.

As a whole, reserpine and its derivatives have decreased in popularity, mainly because patients with long institutional records frequently have a low blood pressure which discourages the use of Rauwolfia. Yet, it is felt that eventually Rauwolfia will claim its definite place among the tranquilizers.

DISCUSSION

NORMAN MORGAN, M. D. (Warren, Pa.).—It is immensely gratifying to discuss a paper such as this one by Dr. Malamud and his colleagues. Past experience has led us to expect from this group only meticulously designed studies which make the results appear deceptively easy. An important body of basic data has been added to the subject of tranquilizing drugs.

We have come to accept the double blind technique and the pooling of clinical evaluation to avoid personal bias as necessities in clinical research. One is curious to know why such a large number as 20% of the original group should have to be dropped. Although 183 patients is a considerable number, it must be remembered that each test group comprised only 15 to 33 cases.

The eternal problem to the research worker is the nature of the questions he should ask. What does he want to know, first, and second what questions must he ask to find the answers. Of the 4 questions that are the basis of this paper, the first 3 are relatively uncomplicated: the rating of the therapeutic effects on 12 symptoms of 6 Rauwolfia derivatives as compared with each other and placebo.

bos, and according to the maintenance of the effect after treatment termination.

The fourth question seeking "specific psychopathological phenomena that are especially likely to be beneficially affected" hints at a larger issue which seems to me to be the significant one raised by this paper. This point is brought out by the authors in their discussion of the results. It was observed that deserpidine, which was consistently low in the comparative rating on its effect on the 12 specific behavior items, nevertheless was judged to have the greatest therapeutic effect in the final general evaluation. The criteria for rating the final evaluation are not clear in this paper. The 12 symptoms assessed do not add up to a total personality. Presumably other criteria are involved in the nature of "one's general impression."

The authors suggest that the high final rating is the result of the beneficial effect of this drug on activity and combativeness, which are benefits considered particularly important by the workers. This being no doubt true, the following question is naturally raised: toward what goal is improvement being rated? Toward social conformity, less noise on a disturbed ward, less autistic activity, better

integration of the total personality? Goals in therapy appear deceptively obvious.

At a certain stage of research, improvement must be measured in terms of specific symptoms. Which symptoms are most informative about the totality of the patient depends largely on one's frame of reference. It may be that as we find basic symptoms which are significant measures of the total personality we can develop greater specificity in seeking and employing drugs. For example, drugs which affect combativeness may affect the total personality functioning more significantly than drugs affecting mutism.

The fact that a drug should apparently show persistent therapeutic benefit 6 to 12 months after it is administered, suggests that it influences not only the symptoms *per se*, but some factor basic to the symptom. It implies some basic personality change that makes combativeness, for example, no longer necessary to the patient.

Although the authors have specifically avoided rating the 12 symptoms as to qualitative importance, it is to be hoped that further analysis of the data will impel them to speculate on this aspect of their observations.

A BIOCHEMICAL EVALUATION OF THE ACTIVITY OF CERTAIN TRANQUILIZERS AND THEIR RELATIONSHIP TO HORMONAL FUNCTION^{1, 2}

MALCOLM GORDON, PH. D., WILLIAM ZELLER, M. D., AND JOHN DONNELLY, M. D.³

INTRODUCTION

While the physiological and biochemical changes now known to be produced by the phenothiazines are many, thus far no theory of their action is adequate to explain, or at least fully explain, their usefulness in psychiatric practice. However, the physiological impact of the phenothiazines on the endocrine systems are perhaps most promising in providing a biochemical rationale for their action.

Chlorpromazine is known to effect pituitary-gonadal function(1); pituitary-thyroid function(2); thyroid function(2); adrenal-cortical function(3); and adrenalin function(4, 5), while clinically lactation and alteration in menstrual function are not uncommon sequelae of chlorpromazine administration.

Studies of the effects of chlorpromazine on some aspects of amino acid metabolism, a function effected by a variety of hormones, will be reported here. Interest in this property of the phenothiazines developed from the work being carried out in our laboratory on the biochemical effects of several hormones on nitrogen metabolism. Elsewhere we have reported on the effects of a variety of hormones on nucleic acid metabolism and protein synthesis(6).

EFFECT OF INSULIN ON SERUM AMINO ACIDS

Among the hormones studied with particular interest was insulin. For some time it had been known that the injection of insulin sharply lowers the concentration of serum

amino acids as well as the concentration of blood sugar(7). We became interested in the question of whether or not the amino acid effect was of any significance in the promotion of certain behavioral changes noted with some schizophrenic patients receiving insulin coma therapy.

First investigated was the possible interdependence of the two phenomena: do amino acids change as a function of glucose change? This question was approached as follows: the coma dose of insulin was established in the usual fashion. Treatment was continued on this dosage together with continuous intravenous injection of glucose given in an amount sufficient to maintain the approximate fasting blood glucose level. During the procedure the patients remained fully alert. The data presented in Tables 1 and 2 demonstrate that the amino acid and glucose effects of insulin are completely separable. The fall in circulating amino acids under the influence of insulin or under the influence of insulin plus glucose are virtually identical.

FATE OF AMINO ACIDS

The question of the fate of the amino acids under conditions of insulin-glucose was then investigated. Elsewhere we have reported that the amino acids are taken up into compounds (nucleic acid-amino acid derivatives) which are probably precursors of protein(6). This effect was demonstrated with rat livers. Table 3 shows something of the variety of amino acids detected by paper chromatography in these nucleic acid-amino acid derivatives, and their increased concentration with insulin. It is not surprising, therefore, that the concentration of the several amino acids in blood under the influence of insulin were approximately equally decreased.

CHANGES IN AMINO ACIDS IN CSF

The influence of this changed physiological state on the nutritional milieu of the brain

was our next concern. While it is recognized that changes in the cerebrospinal fluid obtained by lumbar puncture do not promptly reflect central nervous system metabolism at higher levels, it was hoped that some indication of the changed physiological picture with glucose-insulin would be demonstrable in the spinal fluid.

Table 5 shows some of the changes in total amino acid nitrogen under the influence of both insulin and insulin-glucose. The spinal fluid appears (at least quantitatively) to reflect the changes in amino acids observed in serum. Detailed analysis of the concen-

tration of the individual amino acids in spinal fluids under varying hormonal stimulations are as yet incomplete, but preliminary experiments suggest that the nature of the changes does not exactly reflect the changes in serum. Studies by other workers⁽⁸⁾ of the transfer of C¹⁴-methionine across the blood-brain barrier in the rat report a fall in transfer rate after injection of insulin. But whether this reflected a drop in efficiency of barrier mechanisms due to glucose deficiency, or the preferential uptake of the methionine in other tissues under the influence of insulin, or whether it represented a specific effect of

¹ 5 mg. Trialaon I.M. Sample taken after 2 hours.² 50 mg. chlorpromazine I.V. Sample taken after 2 hours.³ 40 mg. chlorpromazine I.V. Sample taken after 2 hours.⁴ In microgram equivalents of glutamic acid/ml. spinal fluid. (Ninhydrin reaction on deproteinized spinal fluid sample.)

phenobarbital, equanil, saline, glucose. Only glucose gave any significant changes, which probably reflects its action on endogenous insulin production.

COMPARISON OF EEG DATA WITH BIOCHEMICAL DATA

Preliminary data in acute human experiments with insulin, several phenothiazines, barbiturates, and equanil, support the suggestion from rat data that the compounds used for sedation and tranquilization fall into two separate categories also; those drugs which have an immediate effect on the serum amino acid nitrogen, *e.g.*, insulin and the phenothiazines, and those which do not, *e.g.*, the barbiturates and equanil (see Table 7). This biochemical distinction may also be measured by the EEG. In concurrent EEG investigations by Henry and Obrist of these laboratories, which will be reported elsewhere, these workers have shown that equanil, when administered to humans in doses of 2 gms. or more, produces fast EEG activity indis-

TABLE 7

EFFECT OF SEVERAL DRUGS ON FASTING SERUM AMINO ACID NITROGEN

Drug	Amount	Number of cases	Time after injection (in hours) 0-1-2-3			
Chlorpromazine ..	50 mg. I.V.	10	4.6 ¹	4.3	4.0	3.7

CHART 2.—Effect of Chlorpromazine on serum amino acid nitrogen.

(Average of 20 cases)

tinguishable from that observed with barbiturates. The phenothiazines do not cause this type of fast EEG activity, nor does insulin in the presence of glucose. This is further evidence suggesting that these different classes of drugs exert their primary effects by influencing different physiological mechanisms.

EFFECTS OF CHRONIC ADMINISTRATION OF PHENOTHIAZINES ON SERUM AMINO ACIDS

In Chart 2 the effects of oral chlorpromazine given for a prolonged period on the level of amino acids in fasting serum are shown. The initial fall in level is soon more than compensated for by some type of "rebound reaction," but a fresh drop can be induced by elevating the level of the drug.

One possible explanation for the "rebound effect" may be as follows: chlorpromazine is known to promote the release of adrenalin from its storage places and eventually cause a deficiency in adrenalin by this means. If it is assumed that the effect of adrenalin on the concentration of serum amino acids is not blocked by the drug, one might anticipate a fall in amino acid level with the first administration (reflecting a temporary increase in blood adrenaline concentration) followed by an increased level of amino acids resulting from the depletion of adrenalin in the organism.

This observation may shed some light on the relative resistance to insulin by patients

receiving insulin coma treatment when the treatment is interrupted on weekends. For example, on Monday mornings the dose effective in producing coma on Friday frequently fails to induce coma. It may be postulated that insulin produces a release of adrenalin which antagonizes the effects of insulin in reducing blood sugar, but the effect becomes less significant as adrenalin stores are depleted.

Finally, observations on the amount of chlorpromazine required to produce a significant fall in serum amino acid nitrogen and the amount required to produce a clinical effect in previously untreated patients indicates that this biochemical measurement is a good index of whether or not sufficient drug has been administered. No significant effects are observed with less than 100 mg. a day orally, with consistent effects demonstrable at 200 mg. a day and above.

These results raise an interesting question. Do the changes in concentration of amino acids produce behavioral changes, or do they merely reflect the biochemical changes significant for the production of behavioral change? The experimental approach to this question is not simple because of the rigorous regulation of the concentration of amino acids in the nutritional milieu of brain by the blood-brain barrier. However, several different experimental approaches which may permit evaluation of the behavioral, the biochemical, and electroencephalographic effects of changed amino acid concentrations in spinal fluid in the absence of added drugs or hormones are planned.

DISCUSSION

HAROLD E. HIMWICH, M. D. (Galesburg, Ill.)—Doctors Gordon, Zeller, and Donnelly have made an impressive discovery in regard to the effect of drug action on the amino acid nitrogen in serum and cerebrospinal fluid of human subjects. They have found that the phenothiazines, like insulin, lower the level of serum amino acids, while the barbiturates and meprobamate do not affect their level. They also report that meprobamate and the barbiturates induce fast waves in the EEG.

The authors point out that the fall of amino acid with the phenothiazines may be caused by an increased concentration of adrenaline available to the tissues because that drug promotes the release of adrenaline from its depots. In view of the fact that reserpine also releases adrenaline, it is desirable to determine whether or not amino acids also decrease with reserpine medication as a test for the adrenaline hypothesis.

The authors may believe that the action of insulin is not evoked by the adrenaline mechanism because it still occurs when glucose is given simultaneously with insulin. It is well known that insulin hypoglycemia evokes a raised level of adrenaline in the blood. But in all of their experiments some fall of blood sugar level was reported and that the levels observed need not necessarily have been the lowest attained. When the medullary portions of the adrenal glands of rabbits are destroyed, insulin fails to produce a decline of serum amino acid nitrogen. (*J. Biol. Chem.* 1934, 104, 207.)

What significance these results have for behavior is to be determined. The authors rightly point out, however, that multidisciplinary studies, like theirs, give the best opportunity for solving the most difficult problem of all, that of human behavior.

THE PHYSIOLOGIC BASIS OF THE MANIC-DEPRESSIVE ILLNESS: A THEORY¹

S. H. KRAINES, M.D.²

It has been generally agreed not only by clinicians like Kraepelin(1), who worked with patients in mental institutions, but also by investigators like Freud(2), who pioneered in psychodynamics of nonpsychotic patients, that a constitutional factor exists in the manic-depressive illness. It is also generally agreed that psychic factors play a major role in the symptom formation. However, psychiatrists differ as to the relative weight and significance of these physical and psychic factors in etiology, symptom formation, and therapeutic value.

It is the purpose of this paper to discuss the role of the physiologic factor in terms of etiology and mechanism.

That physical agents influence mood is common knowledge. Physical activities, drugs, organic diseases, experimental stimulation of the brain will elevate or depress the mood.

In the manic-depressive illness, extensive clinical experience indicates that:³

1. The onset occurs in the archetype form in the absence of precipitating or predisposing factors;

2. A consistent pattern (frequently cyclic) is followed by the illness, with a characteristic sine wave curve and fluctuations, despite highly dissimilar psychic backgrounds;

3. There is spontaneous recovery without psychotherapy;

4. Psychotherapy rarely shortens the illness and rarely prevents the recurrence of attacks;

5. A physical agent such as electric shock frequently produces recovery from an attack.

As in any disease process there are many deviations from the classical form; so in the manic-depressive illness there are many variations

in which psychic factors appear to be etiologic. In the classical archetype form, however, the onset, course, and termination strongly indicate a physiologic etiology. The depressive cycle may have an insidious or precipitous onset, and is characterized by fluctuations which are most intense in the middle zone (see Chart 1) and least in the lowest zone. The curve descends through phase 1 of boredom and dissatisfaction, through phase 2 with marked irritability and depression, into phase 3 of complete apathy and intense melancholia. Occasionally, agitation replaces apathy. Passing the nadir, the curve ascends through phase 4, still of apathy, into the intensely irritable and markedly fluctuating phase 5, thence into the terminal phase (6) where there is improved social adjustment despite a sense of inadequacy. The entire cycle has an average duration of 18 months, with variations from a few days to many years. The manic cycle is a mirror image of the above, but averaging 4 to 6 months in duration. The curve ascends through phase 1 of hypomania where the patient is usually regarded as normal though erratic, into phase 2 of manic excitement usually requiring hospital care, into phase 3 of delirious mania where there is danger of death from exhaustion. After the zenith, the patient descends through comparable phases to his normal level.

Some patients have mild depressive attacks which rarely dip below phase 1; many have mild hypomanic attacks which rarely climb above phase 1. A large number have only depressive attacks in their life time, and many have only one such attack. Others have alternating attacks of manic and depressive swings occurring at 6 month intervals. There are innumerable variations and combinations.

The pattern of these cycles, in the archetype form, is characteristic for most patients; the attacks are minimally modified by psychic trauma or psychotherapy; their entire pattern is that of a physical illness, with psychic overtones.

Fluctuations in the
Manic Depressive Cycle

CHART I.

Two additional factors support this thesis: hereditary susceptibility and endocrine imbalance. Numerous studies (Kraepelin (1), Banse(3), Rudin(4), Luxenburger(5), Lewis(6)) point to the significant influence of heredity in this disease. Kallman's(7) studies on identical twins show (and his figures are supported by those of other workers) that in the relatives of manic-depressive patients the incidence of the same illness in the parents is 24%, in the half siblings, 16.7%, in the full siblings 23%, in the dizygotic twins 26.3%, and in the monozygotic twins 95.7%.

SUMMARIZING TABLE OF HEREDITARY INCIDENCE OF MANIC-DEPRESSIVE ILLNESS

Combined figures for the relatives of patients show an incidence of 24% in the parents (Kallman); 16.7% in half siblings (Kallman); 23% in full siblings (Kallman, Rudin); 26.3% in dizygotic twins (Kallman), 16.4% in dizygotic twins (Rosanoff); 95.7% in monozygotic twins (Kallman); 69.6% in monozygotic twins (Rosanoff); 2.3% in cousins (Luxenburger); 3.4% in grandchildren (Luxenburger).

Hormonal factors in the etiology are indicated by the large number of manic-depres-

sive attacks following childbirth (Boyd(8)). Whereas psychic factors in pregnancy are undoubtedly of importance, the frequency of a background of hereditary susceptibility in these patients, the sudden onset of symptoms in the majority of patients shortly after childbirth despite the long presence of the psychic stresses, the occurrence of the illness after one pregnancy and not another, the subsequent recurrences unrelated to pregnancy; all indicate a physiologic factor. Almost 9% of all females who suffer from psychoses of various sorts develop their mental disorder in connection with pregnancy (Bellak(9)). The premenstrual intensification of symptoms, the relationship to the involutional period, and the preponderance of females over males in the ratio of 2 to 1 also emphasize the influence of hormonal changes in this illness.

The question arises, in view of this constitutional or physiologic factor, as to the site of the physiopathology. Since the symptomatology of the manic-depressive illness is psychic and psychosomatic, the central nervous system must be involved. The major organ systems of the brain include: 1. the extrapyramidal system; 2. the frontal lobes; 3. the rhinencephalic complex; 4. the cerebral cortex; 5. the diencephalon; and 6. the midbrain

reticular system. Analysis of the known functions of these systems provides significant clues. The extrapyramidal system which includes the basal ganglia and the cerebellum is primarily concerned with motor dysfunction, and disease of these areas (Parkinsonism, tumors) results in motor and not in primary mood disturbances. The frontal lobes, which anatomically and functionally are related to the rhinencephalon and the cerebral cortex, are described separately in terms of the popularity of "psychosurgery." Diseases of the frontal lobes (general paresis, encephalitis, tumors) are associated with minor personality changes and only secondarily with mood changes. Removal of the frontal lobes has little effect on the mood swings of psychotic patients, and minimal effect on the mood of other psychiatric patients. Tension and obsessive states are often relieved by section or ablation of the frontal lobes but the depressive or elated mood remains untouched.

The rhinencephalon (limbic system), originally considered a vestigial remnant of the olfactory system, has been shown by Papez(10) to be intimately involved in the emotional process. According to him "the hypothalamus, the anterior thalamic nucleus, the gyrus cinguli, the hippocampus and their connections constitute a harmonious mechanism which may elaborate the functions of central emotion, as well as participate in emotional expression." Kluver(11) in experiments on monkeys finds that surgical interference in this area results in emotional changes, and concludes that the hippocampus represents a "catalytic activator" basic for the proper functioning of affective and neocortical activities. Ward(12) finds that ablation of the anterior portion of the gyrus cinguli results in loss of fear. Pribram and Kruger(13) find that the amygdala and adjacent cortices are intimately related to emotional function. Fulton(14) concludes that the "orbito-insulo-temporo-cingulate complex is concerned with emotional expression, whereas lateral elements of the neopallium are primarily concerned with learning, memory, and intellectual functions." Since it appears, therefore, that the rhinencephalic complex is intimately associated with the

elaboration of emotion, it can be postulated as a physical site of manic-depressive illness.

The hypothalamus has at least 3 related functions. It is a major station of the autonomic nervous system, the posterior portion being strongly sympathetic, and the anterior portion being strongly parasympathetic (Gellhorn(15), Hess(16)), and in this way influences the visceral system. It also contains many nuclei which have specific functions: centers affecting glands of internal secretion, vasomotor centers, a temperature regulating center, a salt and water regulating mechanism, a sleep-waking center (Ranson(17)), and an appetite center (Kennedy(18), Anand and Brobeck(19)). In addition, sham rage and other peripheral expressions of emotion occur as a result of hypothalamic activity (Bard(20), Gibbs and Gibbs(21)). Several authors (Foerster, (22), Fulton(23)) have reported manic-like reactions when the hypothalamic area was manipulated during surgical procedures. The hypothalamus is thus a potential source of psychosomatic symptoms as well as of the expressions of emotion.

The thalamus (Chart 2) is primarily a receiving station for afferent impulses from the body and the external world. The medial lemnisci carry fibers of position sense; the spinothalamic tract transmits pain and temperature; the trigeminal tract mediates sensation from the face, all terminating in the thalamus. The optic and auditory fibers terminate in the meta-thalami (the lateral and medial geniculate bodies). Since emotion

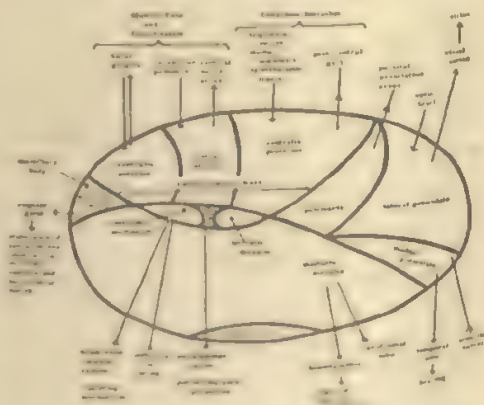

CHART 2.

is fundamentally dependent on sensory experience, a thalamic disturbance will be reflected in emotional disturbance. Moreover, many of the disturbances in sensation which manic-depressive patients experience, such as paresthesias, blurring of vision, disturbances in hearing, changes in taste, disturbance in the sense of balance will also result if there is a disturbance in thalamic function.

Consciousness ranges from a physical condition of simple alertness, at one extreme, to highly complex psychic awareness, at the other. The consciousness of the decorticated animal is little more than physical alertness: the consciousness of the normal animal permits him to remember and choose his responses. Penfield (24) has ably described the continuation of consciousness no matter how large an area of the brain is destroyed as long as the central core of the brain (the centrencephalon) remains intact. Magoun (25) and others have demonstrated that the reticular system in the upper brain stem is intimately related to this state of awareness, and that the activity of this reticular system is essential in the maintenance of consciousness. Consciousness, in these terms, applies to the physical level of alertness, a highly organized stimulus-response mechanism. Such "alertness" is a prerequisite for but not identical with man's intellectual and emotional appreciation of stimuli. Once this state of alertness is achieved, then the cerebral cortex can begin to supply the content of consciousness; should the reticular system function inadequately, there would be a "clouding" of consciousness. Manic-depressive patients complain often of "being in a daze," of "things being unclear," of "decreased alertness." Concentration is difficult with decreased alertness and attentiveness.

It follows that a physiologic (and reversible) dysfunction in the diencephalic area (the hypothalamus, the thalamus, the rhinencephalon, and the reticular system) (Chart 3) can account for most of the symptoms found in the manic-depressive illness. The psychosomatic symptoms and the peripheral manifestations of emotional disturbance could result from hypothalamic dysfunction; the alteration in sensory experience

on the thalamic level would explain many of the sensory disturbances found in these patients, and would also explain the alteration in the emotional experience which is dependent on physical sensation. A disturbed function in the rhinencephalon, which appears to act as an emotion elaborating mechanism integrating the diencephalic reactions with the cerebral cortex, would result in further distortion of the emotions. A change in the activity of the reticular system would bring about an impairment of consciousness and an alteration in the degree of alertness and energy output with which the cerebral cortex can respond to stimuli.

CHART 3.

Schematic Concept of Biologic Basis of Emotion

Interceptive (visceral) and exteroceptive stimuli (somatic sensory) arrive in the thalamus (lateral nuclear masses and the geniculate bodies). These stimuli, integrated in the thalamus, pass a. directly to the cerebral cortex, b. directly to the hypothalamus, and c. via the rhinencephalon (limbic system) (cingular gyri, hippocampus) to the mammillary body (M), and to the cerebral cortex. The hypothalamus manifests the physical signs of emotion (dilated pupils, hypertension, spasm of smooth muscle, etc.) directly through the autonomic nervous system and indirectly via the pituitary. The cerebral cortex becomes "aware" of the specific nature of the stimuli. The rhinencephalon acts as a reverberating neuronal mechanism elaborating the sensory stimuli into the quality of "emotion" on a biologic level, the cerebral cortex, interacting with the rhinencephalon, is the seat of the "conscious" quality of emotion. Psychodynamic mechanisms, with their physical basis in the cerebral cortex, but governed by relatively independent principles, derive their emotional quality from the activity of the diencephalic area. The reticular system acts as a non-specific "alerting" mechanism for the cerebral cortex.

The role of the cerebral cortex in the manic-depressive states remains to be examined. In terms of specific functions such as mediated by the post central gyri, the visual and auditory cortices, the precentral gyri and Broca's area, the cerebral cortex is not involved since these cortical functions remain intact. In terms of purely intellectual functions such as are involved in memory, orientation, ability to calculate, etc., the cortex is not primarily involved. In physical diseases of the cerebral cortex whether they be of the infectious variety or a result of abiotrophy and sclerosis, manic-depressive reactions are secondary if they occur at all. The preponderance of evidence would seem to indicate that the cerebral cortex is not primarily disturbed and consequently is not the primary site of the manic-depressive illness.

The cerebral cortex is, however, secondarily involved. Dependent upon stimulation from the lower centers in the diencephalic area, the cerebral cortex suffers from an inadequate alerting by the diseased reticular system and receives unusual stimulation from the disturbed function of the thalamus. In consequence, the distorted intero- and exteroceptive sensations which are perceived in consciousness appear different from usual. This alteration in sensation creates a state of alarm which is then expressed as the "free-floating" anxiety so characteristic of manic-depressive patients.

Once the cerebral cortex is so stimulated, psychodynamic laws begin to operate; and such psychologic mechanisms as rationalization, repression, and projection bring about a host of symptoms which vary from patient to patient. Consequently, latent feelings of guilt, rationalizations as to cause, symbolic expressions by various phobias, and vague projection phenomena may occur. It must be emphasized, however, that these psychodynamic reactions which draw their material from the patient's past experiences and his patterns of reactions, are secondary reactions, secondary to the physiologic disturbance of the diencephalon-rhinencephalon-reticular system.

Clinically, in the archetype form, the intensity of the symptoms follows a sine wave

pattern, with many superimposed fluctuations. As the physiopathology intensifies, so do the symptoms; after the nadir of the depression (or the zenith of the manic state) has been passed and the spontaneous and self limiting disease process begins to improve, so also do the symptoms.

In the days before modern psychiatric procedures, these patients would be hospitalized and with only palliative therapy there would be, in the vast majority of patients, a spontaneous recovery in 6 to 18 months. The psychiatric approach today has a two-fold purpose: 1. physiologically to assist in the recovery from the disease process, primarily by the use of some of the newer drugs and by electric shock therapy; and 2. by means of psychotherapy to enable the patient not only to dispel the secondary psychopathology, but also to help him remove the distortions of his premorbid personality.

SUMMARY

Clinical experience and studies of heredity indicate that the etiology of the manic-depressive illness is physiologic. Examination of the possible sites of the physiopathology implicates diencephalic-rhinencephalic-reticular brain systems. It is the secondary involvement of the cerebral cortex that results in psychopathology. Psychodynamic mechanisms use the patient's experiences and reaction patterns in the formation of symptoms. As the physiopathology spontaneously improves, so do the symptoms.

STUDIES IN HUMAN ECOLOGY

FACTORS RELEVANT TO THE OCCURRENCE OF BODILY ILLNESS AND DISTURBANCES IN MOOD, THOUGHT AND BEHAVIOR IN THREE HOMOGENEOUS POPULATION GROUPS¹

LAWRENCE E. HINKLE, JR., M.D., NORMAN PLUMMER, M.D., RHODA METRAUX, PH.D.,
PETER RICHTER, M.D., JOHN W. GITTINGER, M.A., WILLIAM N. THETFORD, PH.D.,
ADRIAN M. OSTFELD, M.D., FRANCIS D. KANE, M.D., LEO GOLDBERGER, M.A.,
WILLIAM E. MITCHELL, M.A., HOPE LEICHTER, M.A., RUTH PINSKY, M.A., DAVID
GOEBEL, M.D., IRWIN D. J. BROSS, PH.D., AND HAROLD G. WOLFF, M.D.²

This is an initial summary of the findings from 3 studies which have been carried out during the past 5 years. Two have been completed; the third is still in progress. Twenty-four investigators from the fields of internal medicine, psychiatry, psychology, sociology, cultural anthropology, and medical statistics have taken part in these investigations with the technical assistance of 8 others. The 3 population groups which have been studied provided a total of 2924 individuals upon which the general conclusions are based.

These studies were designed to investigate the influence which man's relation to his social environment has upon his health. They are based upon the premise that in a group of people unselected with regard to health, and essentially equal with regard to the various factors known to affect health, each individual's relation to his own life situation is an outstanding variable. In such a group, a study of the relationship between this variable and the state of health of the individual members is facilitated. It is not possible, of course, to obtain any group of human beings which is literally homogeneous with regard to all of the various factors which may affect the health of its members. One can, however, find groups which closely approach homogeneity with regard to the major factors, and in which the minor and unrecognized factors are presumably scattered at random, thus minimizing the influence of these variables as compared to the variable under study.

Among the major factors that are known to have an effect upon the health of humans are age, sex, genetic inheritance, constitution, the effects of previous disease processes, cultural background, socio-economic status (with all that this implies in terms of diet, housing, etc.), occupation, the general physical environment, and the opportunities for encountering the external causative agents relevant to disease. We have studied 3 groups, each quite different from the other 2, and each remarkably homogeneous with regard to most of these factors. The genetic inheritance and constitution of individual members, of course, cannot be controlled; but the effect of this and other variables can be assessed to some extent by a consideration of the individual case material, as will be described later.

The characteristics of these 3 groups are outlined in Table 1. There were independent and complete records of all the periods of disability, and of the nature of all illnesses, which had occurred in the adult lives of the members of the two American groups, both of which were employed by a corporation that kept meticulous records of its employees' health and attendance. In the Chinese group we were forced to rely upon the medical histories given by the informants, their descriptions of the symptomatic manifestations of their illnesses, and the results of physical examinations and diagnostic tests, in order to obtain our information about their health. Information obtained in this manner from the American informants, when compared with that obtained independently from their records, was found to be reliable, and it is our belief that we have a reliable estimate of the health of our Chinese informants.

In the 2 American groups the following

TABLE 1

CHARACTERISTICS OF THE THREE GROUPS

	Group I	Group II	Group III
1. Total number studied.....	1297	1527	100
2. Number studied intensively.....	336	279	100
3. Age	17-50	17-55	19-72
4. Sex	Women	Men	Men and women
5. Cultural background	2nd Generation Irish and Italian American	Mixed indigenous American	Chinese
6. Socio-economic background.....	Upper-lower class	Lower-middle class	Upper class
7. Education	Grammar school	High school	College
8. Occupation	Unskilled white-collar	Skilled workmen	Graduate students pro- fessional men
9. Lifetime environment	Metropolitan New York	Metropolitan New York	Various parts of China (Later United States)
10. Sanitation of general sur- roundings	Generally high	Generally high	Generally very low
11. Exposure to pathogens and trauma	Low	Moderate	High
12. Physical deprivations, pres- sures and dislocations	Few	Few	Many
13. Social dislocations and situ- ations of uncertainty	Few	Few	Many

investigative procedure was used: the initial group was made up of all people employed in the same type of work in a division of a corporation in a large city—approximately 1,800 men in one case and approximately 1,700 women in the other. From these initial groups there were excluded all those for whom complete records were not available, leaving 1,527 men and 1,297 women. These larger groups were used for statistical studies of the distribution sickness disability and the occurrence of various illnesses among their members, over a number of years.

There were many women and men who had been observed continuously for 20 years or more. All of these women (336) and one-third of the men (279) were studied intensively, using statistical methods. When the distribution of illness over a 20-year period in these 2 smaller groups had been obtained, the 20 in each group who had been disabled for the greatest number of days, and the 20 disabled for the smallest number of days, were identified. The records of these 40, and those of many others selected at random from the middle range of each group, were examined carefully to ascertain the nature of the illness episodes which had been experienced. The informants, themselves, were interviewed by an investigator who obtained from them a complete medical history, and carried out a physical and psychiatric ex-

amination, as well as additional diagnostic procedures if any were necessary in order to complete his understanding of the case. At the same time, a life history was obtained covering the pertinent aspects of the early development and later life experiences of the informant.

A somewhat different procedure was used with the Chinese. All members of this group of 100, selected at random from a larger group of approximately 5,000 Chinese graduate students and professional men, were studied intensively for a total of 16 hours. Four hours of this were spent with an internist, 4 hours with a psychiatrist, 4 hours with a cultural anthropologist and sociologist, and 4 hours with a clinical psychologist, who administered a battery of tests including the Wechsler-Bellevue Intelligence Scale, Form I, the Rorschach Test, the Lowenfeld Mosaic, a Projective Questionnaire, the Sacks Sentence Completions, the Thurstone Temperament Scale, and Human Figure Drawings. The TAT was given to about 30 of the informants also.

Sickness disability was not distributed at random among the members of any of these groups. In each group there were many members who had more illness, and many who had less illness, than would be expected if chance alone were the determining factor. In the group of American men, upon whom

the statistical studies are most complete, the distribution of sickness episodes closely approximates the negative binomial distribution—a distribution which is based upon the assumption that some factor in addition to chance determines the occurrence of such episodes. In this group, approximately 10 percent of the men show a statistical "risk" of becoming ill which is at least twice as great as the average "risk" for the group, and another 10 percent show a correspondingly smaller "risk" (Fig. 1). The general effect of this skewed distribution of illness is that approximately one-fourth of the individuals experienced more than half of all the illnesses and upwards of 75 percent of the total days disability.

Our general inference from this finding is that, in all of these groups, some factor other than chance determines the occurrence of sickness in the individual members. Since this appears to be a consistent finding, we suspect that the same phenomenon occurs in the population at large.

An investigation of the nature of the illnesses experienced by the various members of each group revealed that in all 3 groups, those who had the greatest amount of sickness disability had experienced a wide variety of illnesses of various types, and various etiologies, involving a number of body systems. While one or two recurrent or chronic illnesses might predominate in the sickness pattern of an individual, it was a universal finding that those who had a great many episodes of illness, and a great many days of total disability, experienced illnesses involv-

ing a number of body systems. This is illustrated in Fig. 2, from the study of the American men, in which the number of illnesses experienced by each informant is plotted against the number of body systems involved. As the amount of illness experienced by each informant increases, the number of involved body systems increases.

There appears to be a similar relationship between bodily illnesses and disturbances of mood, thought, and behavior. Figure 3, taken from the study of the Chinese, illustrates this. Those having the greater number of bodily illnesses, regardless of their nature or etiology, in general, experience a greater number of disturbances of mood, thought, and behavior.

Between major and minor illnesses, the same type of relationship appears to hold. In each group, those experiencing the greater number of minor illnesses in general experience the greater number of major illnesses. Usually it was found that major illnesses involved the same body systems most frequently involved in minor illnesses. For example, individuals having a great many colds appear to be more likely to have an episode of pneumonia, and those having many minor disturbances of mood, thought, or behavior appear to be more likely to have major disabling illnesses in this category. But major illnesses may appear in other body systems also; the general relationship is shown in Fig. 4 which is taken from the study of the American men.

An example of the illnesses experienced by a frequently ill informant is shown in Table 2. This American working woman was selected for intensive study because she had had 1,041 days of sickness disability over a period of 35 years.

Our general inferences from the foregoing findings are that humans, when they move from a state of "health" into a state of "sickness" are likely to manifest disturbances of function and pathological processes involving a number of body systems. If illness persists long enough, it is likely to be manifested by disturbances in a majority of body systems, as well as by disturbances of mood, thought, and behavior. We infer that whatever factors are responsible for this operate upon man as a whole and influence illnesses

regardless of their nature or etiology. They evidently influence irreversible pathological processes as well as reversible disturbances of function, and diseases which are potentially fatal as well as those which are usually transient and relatively harmless. They influence the occurrence of disturbances of mood, thought, and behavior and the occurrence of bodily illnesses in a roughly parallel manner. The relation between these two categories of illness thus appears to be one of general parallelism. As a group, those who have more of one are likely to have more of the other.

When the distribution of illness in the lives of our informants was studied, it was found that sickness episodes frequently appeared in clusters; usually they were not distributed at random throughout a lifetime. Typically, an informant would have periods of relatively good health, alternating with several years during which he would have a number of illnesses of a variety of etiologies and involving several body systems, running consecutively or concurrently. This is a common phenomenon in all 3 groups, and it ap-

pears to be uniformly distributed in each. It occurs among those who have small and intermediate amounts of illness as well as among those who have many illnesses. Some illnesses and accidents do, of course, appear as isolated phenomena; but most illnesses seem to occur in clusters. An example of this is shown in Fig. 5 taken from the study of the Chinese.

From this phenomenon of "clustering," we infer that whatever factors are operating to affect the general susceptibility of our informants to illness do not exert a constant influence at all times. Their effect is greater at some times, and less at others. There is no predictable period of life when such clusters appear, and they have no consistent duration or magnitude. From this we infer that these factors probably arise out of some changing and unpredictable relationship between each individual and his environment.

By correlating events and situations in the life histories of our informants with the occurrence of clusters of illness, we have attempted to ascertain what consistent features of the individual's relationship to his envi-

FIG. 5

ronment might be associated with fluctuations in his general health. So far as we have been able to determine, physical hardship, geographic and climatic change, and changing exposures to toxic or infectious agents, are not the significant variables. Only occasionally does it appear that the development of an isolated illness, or a cluster of illnesses, is simply the result of some fortuitous encounter with bacteria, trauma, or other influences arising from the physical environment. Genetic inheritance and constitutional endowment undoubtedly play a role in general susceptibility to illness, and probably have an important influence upon the total sickness experienced by an individual throughout his life. But the data in general suggest that, as compared to the effects of the life situation, these factors are relatively unimportant in determining the distribution of illness in any of the groups. In any case, it is difficult to invoke them as an explanation of the clustering of illness at special times in the lives of individual informants.

We find that clusters of illness usually are associated with periods when an individual is attempting to adapt to a difficult life situation (Figs. 6 and 7). That is to say, such clusters commonly occur during periods of demonstrable conflict with parents, siblings,

or spouse, threat to social position, loss of significant supports, or excessive demands created by the sickness or aggressive behavior of other members of the family, employers, associates, and so on. Such observable difficulties in the relationship to the social environment are usually directly stated by the informants to be difficult or unpleasant, with a detailed description of why they are difficult and with appropriate feelings. From such data alone it is possible to say that, in each of these informant groups, the relationship of the informants to their social environment has an important influence upon the occurrence of clusters of illness, and that it is much more consistently related to this than any other factors which have been considered. But the correlation between clusters of illness and such "objective" evidences of difficult life situations is by no means complete. There are a great many instances of informants existing in what are objectively "difficult life situations," with no observable evidence of illness; and, conversely, there are many other instances in which clusters of illness appeared in the lives of informants at times when they were existing in what objectively appear to be benign life situations.

It is axiomatic that man does not react to his environment as it is "objectively" perceived by other people; rather he reacts to it, as he, himself, perceives it in terms of his own needs and aspirations (using "perceive" to include both conscious and unconscious processes). There is no way to ascertain how a man perceives his life situation without using his own subjective impressions, or the inferences of an observer, or both. Information obtained in this manner is always biased by the attitudes of the informant, and is very likely to be biased by those of the observer. Such information, therefore, does not lend itself to being counted or quantified in a mathematical fashion. On the other hand, the observer can validly state his inferences and present the original case material upon which these inferences are based. It has been the general inference of all of the observers who have participated in these studies that the great majority of the clusters of illness which have occurred in the lives of our informants have occurred during life situations which the informant himself perceived as stressful, even though this situation might

CHINESE STUDY

ILLNESSES EXPERIENCED BY ONE INFORMANT

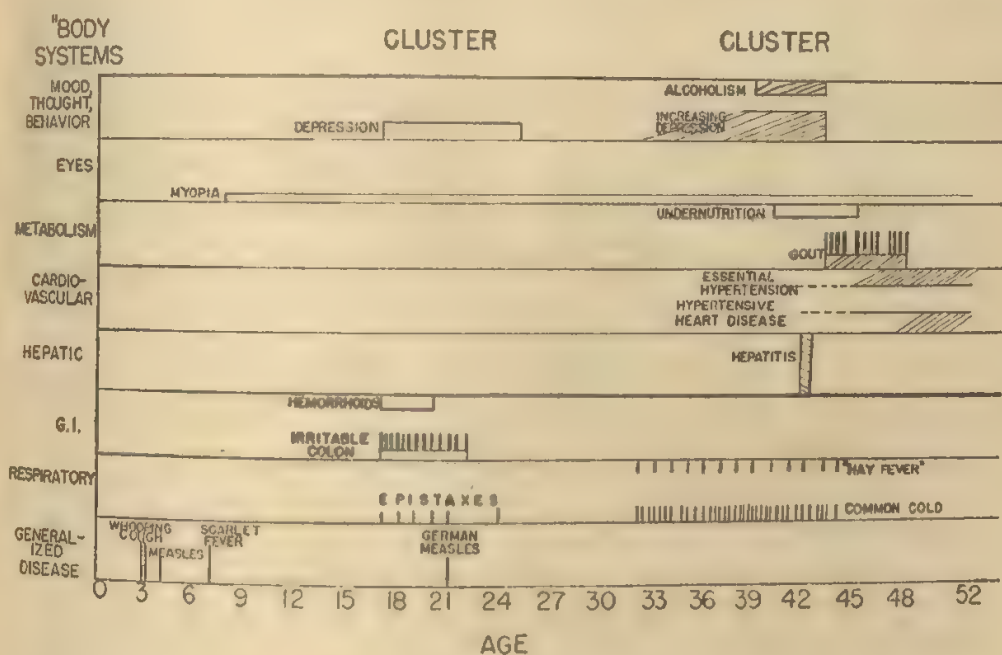

FIG. 6

CHINESE STUDY

RELATION BETWEEN LIFE SITUATIONS AND CLUSTERS OF
ILLNESS IN ONE INFORMANT

FIG. 7

appear benign to an "objective" observer; conversely, when "objectively" difficult life situations are not associated with illness the informants usually did not perceive these life situations as difficult, even though the observer might expect them to do so. This was a consistent observation among the informants in all of the groups, regardless of their general state of health.

CONCLUSION

Our inferences from our studies are these: man's relation to his social environment as

perceived by him has a profound effect upon his general health. It influences the development and progression of all forms of illness, regardless of their nature, and regardless of the influence of other etiological factors. Its effect often far outweighs the influence of changes in the physical environment and the effects of random exposure to pathogenic or noxious agents. As a group, those who are experiencing difficulty in adapting to their social environment have a disproportionate amount of all of the illness which occurs among the adult population.

SOME INTERRELATIONS OF SOCIAL FACTORS AND CLINICAL DIAGNOSIS IN ATTEMPTED SUICIDE: A STUDY OF 109 PATIENTS¹

ELI ROBINS, M.D., EDWIN H. SCHMIDT, M.D., AND PATRICIA O'NEAL, M.D.²

As part of a study of attempted suicide(1), the social difficulties described by these patients who had attempted suicide were investigated by direct interview of the patients. A high prevalence of such difficulties was found, as has been reported in other studies of attempted suicide(2, 3, 4). The emphasis in this study has been on investigating the interrelations between the diagnosis in a given patient and the social difficulties which he reported. The diagnostic groups studied were compared with regard to the prevalence of broken homes from which they came, suicide in their families, adequacy of the patient's past and present social adjustment, the social stresses to which the patients had been subjected just prior to the suicide attempt, and the social context of the suicide attempt itself, i.e., the content and nature of his emotional state at the time, the main reason he gave for making the attempt, and whether the patient was alone at the time of the attempt.

This comparison by diagnostic groups revealed important differences in these factors between the patients with manic-depressive psychosis on the one hand and those with chronic alcoholism, conversion reaction, or sociopathic personality on the other hand. Other findings were the complete absence of any patient who was psychiatrically well (normal) prior to his attempt and the complete absence of any patient with an anxiety reaction. These findings will be discussed with regard to the interaction between social difficulties and a clinical psychiatric illness in leading to suicide attempts.

METHOD OF STUDY

Our observations were made on 109 patients who were brought to a large general

¹ Read at the 112th annual meeting of The American Psychiatric Association, Chicago, Ill., April 30-May 4, 1956.

² From the department of psychiatry and neurology, Washington University School of Medicine, St. Louis, and the St. Louis City Hospital (Malcolm A. Bliss Psychopathic Institute).

hospital immediately after having made a suicide attempt. The method of selecting the patients, the method of obtaining data about them, the diagnostic criteria, and the authors' evaluation of the seriousness of the suicide attempt have been described in detail(1). All patients were examined by means of an open-ended questionnaire which covered past and present medical history, details about the suicide attempt, and a personal and social history. The personal and social history included information concerning the parental home, school history, work history, income, change of residence, marital history, legal difficulties, arrests, drinking history, military service, and the nature of the patient's relationships with family members, friends, and job associates. Social factors in the suicide attempt itself were investigated by means of inquiries concerning the "main reason" the patient made the attempt, possible disturbing events and symptoms occurring prior to the attempt, and the patient's emotional reaction at the time of the suicide attempt. (See questions 1 through 49 in a previous paper(1).)

In this report, a detailed comparison of 86 patients in 5 diagnostic categories—manic-depressive depression, chronic alcoholism, conversion reaction (hysteria), sociopathic personality (psychopathic personality), and patients in whom a definite diagnosis was not made, the undiagnosed group—is presented. Manic-depressive depression in this study includes involutional melancholia and psychotic depressive reaction, i.e., manic-depressive depression will be used even if the patient did not have a prior psychotic depression or manic episode(1). There are 23 patients who will not be discussed in detail. Of these 23 patients, 8 (those with acute brain syndrome and chronic brain syndrome) have already been discussed in a study of attempted suicide in old age(5). The remaining 15 patients included 6 with schizophrenia, 3 with drug addiction, and 6 patients with other psychi-

atric diseases(1). These latter diagnostic groups were omitted because they each contained too few patients for statistical treatment.

Patients whose symptoms, course, and signs did not allow an unequivocal diagnosis to be made were placed in the undiagnosed group. A question considered here was whether any of the 21 patients in the undiagnosed group had been clinically well (normal) until shortly before the suicide attempt.

This paper will consider the interaction of social factors with clinical diagnosis in patients who attempt suicide. In dealing with this interaction it was convenient to describe separately: 1. the extrinsic social difficulties which the patients experienced during their lives and just before the suicide attempt, and 2. their emotional state for some time prior to and immediately before the suicide attempt. The first category concerns the presence or absence of objective and extrinsic social difficulties. These socially oriented difficulties include (a) problems in on-going personal relationships because of friction involving spouse, family, friends, or fellow workers, (b) inability to meet normal social demands as evidenced by financial dependency, job instability, legal difficulties, and excessive drinking, and (c) the response to the death of a person important in the patient's life. The second category concerns the emotional state (feelings) reported by the patients. These feelings were classified in 2 ways: (a) feelings about self, such as depression, disgust with self, and worthlessness, and (b) feelings directed towards other persons, such as anger, spite, frustration in

a personal relationship, and a desire to gain attention. This distinction between feelings about self and feelings directed towards others and between the presence and absence of socially oriented difficulties is not meant to imply that a particular behavior or emotional state, *e.g.*, excessive marital friction or feelings of depression, is primarily a reaction to the patient's social environment independent of psychiatric illness or primarily a symptom of his psychiatric illness.

Statistical methods used have been described(1). A significance ratio of 2.0 or greater, corresponding to odds of about 20 to 1, was accepted as being statistically significant.

RESULTS

General Characteristics of the Entire Group (Table 1).—The 86 patients who will be discussed were in 5 different diagnostic groups. There were differences in the sex distribution and average ages in each diagnostic group (Table 1). At least 85% of the patients in each diagnostic group had completed the 6th grade. In the undiagnosed group 33% had graduated from high school, as compared with 5 to 12% in the other groups. In general, the current marital status of the groups did not differ appreciably except that there were fewer separations (3%) and divorces (0%) and more widows and widowers (25%) in the manic-depressive group. In the entire group of 86 patients, 52% were married, 15% had never married, 18% were separated, 8% were divorced, and 7% were widowed.

TABLE 1
AGE, SEX, AND DIAGNOSIS OF THE PATIENTS

Sociopathic personality	8	24.3	17-34	8	22.4	17-26	16	23.3	17-34
Total †	36			50			86		

* The numbers of patients in manic-depressive group and chronic alcoholic group differ slightly from those in the first paper in this series(1) for reasons already stated(5).

† There were 100 patients in the entire study. Twenty-three patients (13 men and 10 women) are not discussed in detail in this paper.

The Undiagnosed Group.—There were 21 patients who did not meet the minimum criteria(1) for any of the diagnoses (undiagnosed group). Special mention of this group is made because unlike the other 4 groups, it does not represent a single clinical entity. It consisted of 12 patients with probable diagnoses of sociopathic personality, conversion reaction, or chronic alcoholism; 2 with a psychosis, either manic-depressive depression or schizophrenia; and 7 in whom a probable diagnosis could not be made. Consideration was given to the possibility that each of these latter 7 patients was clinically normal prior to his suicide attempt. Each of these 7 patients, however, had had no fewer than 4 psychiatric symptoms for at least a year before his attempt and was therefore probably not clinically well during this time.

Prevalence of Broken Homes (Table 2).—In this study broken home signifies death of a parent, a permanent separation of the patient's parents, or a temporary separation lasting at least 6 months, prior to the patient's 16th birthday. The prevalence of broken homes in each of the diagnostic groups was striking. The minimum figure was 47% in the manic-depressive group and the maximum figure was 86% in the patients with sociopathic personality. This high prevalence of broken homes in patients who attempt suicide has also been reported by Batchelor(3). Of the causes of broken homes noted in Table 2, there are 3 that suggest familial maladjustment as causes: divorce, separation, and jail. When these 3 are considered as reasons for the home breaking-up, then a striking finding is evident: patients with manic-depressive psychosis less frequently came from homes disrupted by divorce, separation, or jail than did patients in any of the other 4 diagnostic groups. Therefore the homes of manic-depressive patients showed less evidence of social maladjustment than did the homes of the other patients.

Suicidal Acts in the Patients' Families.—There was a family history (parents, siblings, and grandparents) of suicide or attempted suicide in 6% of the patients with manic-depressive psychosis, 12% with chronic alcoholism, 31% with conversion reaction, 10% of the undiagnosed group, and

TABLE 2

PREVALENCE OF BROKEN PARENTAL HOMES BEFORE
SIXTEENTH BIRTHDAY

6% with sociopathic personality. The high figure in the families of patients with conversion reaction is of interest.

Previous Adjustment of the Patients (Table 3).—Inspection of Table 3 reveals that, in general, the manic-depressive group showed much less evidence of previous maladjustment than did the other 4 diagnostic groups. This is especially remarkable when it is remembered that the manic-depressive patients were significantly older than the remainder of the patients. In every area of adjustment the sociopathic personality patients showed more evidence of disturbance than did the manic-depressive patients. When the 3 other diagnostic groups were compared with the manic-depressive group the following striking differences were evident: the patients with chronic alcoholism had a higher prevalence of marital difficulties, previous hospitalizations, and arrests; the patients with conversion reaction had a higher prevalence of divorce, general hospitalizations, previous suicide attempts, and poor job history; and the undiagnosed patients had a higher prevalence of marital difficulties, general hospitalizations, poor job history, and arrests.

Although the patients with chronic alco-

holism, conversion reaction, and sociopathic personality, and those without a diagnosis, showed differences in some areas of previous adjustment, they resembled each other more closely than any one of them resembled the manic-depressive group.

THE SUICIDE ATTEMPT

Main Reason for the Attempt.—After each patient described his suicide attempt and the circumstances surrounding it, he was asked what he felt was the "main rea-

son" for his attempt. These answers were categorized as indicated in Table 4. The most striking finding was that manic-depressive patients gave as a main reason a much lower frequency of socially oriented reasons than did the other 4 groups and a much higher frequency of delusions and of feelings of depression. The patients described their main reasons as follows: the manic-depressive patients, "Pain in my mouth so bad nobody could help me" (somatic delusion); "Tired and couldn't sleep"; "I

TABLE 4
MAIN REASON GIVEN BY THE PATIENT FOR MAKING A SUICIDE ATTEMPT

* When a patient stated that he was depressed or disgusted but not in relation to any of the socially oriented factors listed above and not in relation to being medically ill or deluded he was scored here. If he stated he was depressed or disgusted for any of these reasons he was not scored under feelings of depression but under the appropriate stress which he believed was causing his depressed feelings and caused the attempt.

couldn't manage things; they were too much for me"; "I was despondent about my (dead) husband"; "I felt bad about my sister dying and wanted to die with her"; from the chronic alcoholics, "No good reason"; "I didn't see any other way—my wife didn't want to live with me any longer"; "To keep from drinking. I was hopeless and nobody cared for me"; "I was mad because my wife didn't want me to drink that whiskey and she was right"; from the patients with conversion reaction, "I didn't want to face my husband when he found out about the rent trouble"; "To show my husband I meant it. I didn't think he believed me"; "I didn't want to live without my baby"; "Everything might be better if I wasn't here"; from the undiagnosed patients, "To see if he cared. I get those terrible headaches and he doesn't seem to worry"; "I was heartbroken about my wife leaving"; "To prove I could do it if I wanted. I wanted to hurt my mother; she keeps reminding me I'm no good. She likes to do this. She treats me like a child"; "Sick and tired of the whole thing—my mother's nagging and my sister trying to run my life"; and from the sociopathic personality patients, "Disgusted as heck about not being able to date Janice"; "On account of being in jail and waiting for my trial (for second armed robbery offense)"; "To frighten my husband"; "Mad, blue, disgusted. My husband was suing me for the kids and I didn't have enough money to fight him. And my boy friend didn't show up"; "To get attention. I just did it."

In patients with conversion reactions and sociopathic personalities and in the undiagnosed patients, the socially oriented reasons given were related chiefly to heterosexual difficulties. In contrast, in the alcoholics these socially oriented reasons were related to drinking itself, and in the manic-depressive patients, to death of a person important in the patient's life. Thus, even when the manic-depressive patients gave socially oriented reasons, they were not those associated with difficulties in on-going personal relationships or with excessive drinking, as in the other 4 groups.

In spite of the fact that the majority of the reasons for attempting suicide offered

by patients in the conversion reaction, undiagnosed, and sociopathic personality groups were socially oriented, almost a fifth of these patients gave profound feelings of depression without a specific social reference as a reason for their attempts. It is often conjectured that such patients are "using" a suicide attempt for some ulterior motive. While this may be true in some cases, it is also true that many are chronically unhappy persons who suffer from recurrent feelings of depression and hopelessness at various times in their lives.

Possibly Disturbing Events and Symptoms during the Six Month Period Prior to the Suicide Attempt (Table 5.)—In addition to the "main reason," we thought it important to ask whether certain specified events, the occurrence of which might have contributed to their suicide attempts, had occurred within 6 months of the attempts (Table 5). Sixteen such factors were investigated systematically in each of the patients (see questions 14-29 in the first paper of this series(1)).

Investigation of these factors revealed that the manic-depressive patients had significantly fewer primarily social difficulties in the 6 months preceding their suicide attempts than did any of the other 4 diagnostic groups. This was even more strikingly demonstrated when the death of a loved-one was excluded and the comparison was limited to difficulties in on-going personal relationships and to evidences of inability to meet the normal social demands (see footnote to Table 5). We believe that this is additional evidence that, in general, the manic-depressive patients lead a less disturbed life than patients in any of the other 4 groups. This finding correlates well with the findings described above concerning the main reasons for the suicide attempts, which indicated that the manic-depressive patients much less frequently gave socially oriented reasons for their attempts.

It was of interest that although difficulties at work (quitting, being fired, being demoted, or excessive friction with boss or fellow workers) and financial problems occurred rather frequently (Table 5) in the entire group, trouble at work was never given as a main reason for suicide, and pov-

* If death of a loved-one is excluded, these figures become 48%, 100%, 100%, 95%, and 100%, respectively. If excessive drinking is excluded, they become 70%, 83%, 100%, 95%, and 100%, respectively.

erty was given as main reason by only 2 patients (Table 4). Whether these 2 difficulties would be more important in a group with a higher social and economic status is not known.

Emotional Reaction at Time of Suicide Attempt (Table 6).—The patients were asked to describe how they felt (their emotional state) at the time of the suicide attempt.

Their spontaneous answers were grouped into 7 categories (Table 6). In addition each patient was asked systematically whether they felt each of these 7 types of emotional reaction at the time of their suicide attempt. The results in Table 6 are based on the total of spontaneous statements plus answers to direct questions.

The first 3 categories concerned feelings

TABLE 6

EMOTIONAL STATE OF THE PATIENTS AT THE TIME OF THEIR SUICIDE ATTEMPTS

Emotional state *	Diagnostic group				Sociopathic personality %
	Manic-depressive depression %	Chronic alcoholism %	Conversion reaction %	Undiagnosed %	
Feelings about self					
Depression	85	60	100	68	77
Worthlessness	55	40	45	53	61
Disgust	75	40	64	63	61
Feelings directed towards others					
Anger	10	20	55	37	38
Spite	10	13	18	32	31
Frustration (in love)	5	7	45	53	46
Desire to gain attention	0	38	0	11	33
Feelings about self <i>only</i>	80	42	25	32	23
Feelings directed towards others <i>only</i>	0	0	0	5	7
Both feelings about self and towards others ..	20	58	75	63	70

* Each of these emotional reactions (states) was asked for independently and scored independently. Only 15 of the 86 patients described only a single emotional state at the time of their attempt; 50% of the patients described a mixture of at least 3 emotional states.

himself and the last 4, feelings directed towards other persons. Even in the 4 diagnostic groups—chronic alcoholism, conversion reaction, undiagnosed, and sociopathic personality—in which a high proportion (more than half) gave externally directed emotional reactions, these were almost always associated with feelings of depression, disgust, or worthlessness. Among the entire group of patients, there were only 2, one undiagnosed and one sociopathic personality, who gave only externally directed reactions. These findings indicate that suicide attempts are rarely made *only* because of feelings of anger, spite, frustration, or desire to gain attention. Even when these elements are present they become associated with feelings of depression, disgust, or worthlessness before the patient makes a suicide attempt. This is additional evidence that suicide attempts, even when they are not sincere attempts to die, are not simply attempts to manipulate the environment but are associated with feelings of self-depreciation and/or depression.

The high prevalence of feelings of depression, worthlessness, and disgust with self in the chronic alcoholic, conversion reaction, undiagnosed, and sociopathic personality groups should not be allowed to obscure the profound difference between patients in these 4 groups and in the manic-depressive group: a much higher proportion of the manic-depressive patients (80%) had *only* feelings of depression, disgust, or worthlessness (without any emotional reactions directed towards other persons) than had patients in the other 4 diagnostic groups—chronic alcoholism 42%, conversion reaction 25%, undiagnosed 32%, and sociopathic personality 23%. This finding is consistent with the data already discussed in which it was shown that the manic-depressive patients much less frequently gave primarily socially directed reasons for their attempts than did the other 4 groups.

Communication of Suicidal Intent.—There were no statistically significant differences among the diagnostic groups in the proportion of patients who had thoughts of suicide prior to the attempt (maximum variation was from 31% of the chronic alcoholics to 53% of the manic-depressive patients) and

in the proportion of patients who had told someone about having suicidal ideas prior to the attempt (maximum variation was from 14% of the undiagnosed patients to 35% of the manic-depressive patients). These data indicate a slight but insignificant trend for the manic-depressive patients to have made a less impulsive attempt than the other 4 groups, *i.e.*, more manic-depressive patients had prior thoughts about suicide and had told someone about these thoughts.

Half of the patients with chronic alcoholism (50%) and with conversion reaction (54%) had made their suicide attempts when another person was present. This contrasted with the manic-depressive patients and the undiagnosed groups where another person was present in only 10% of the cases in each group. The sociopathic personality patients were intermediate between these extremes—25% made their attempts in the presence of another person.

Influence of Age and Sex of the Patients.—The distribution of the sexes in the manic-depressive, undiagnosed, and sociopathic personality groups was not significantly different (Table 1). Any contrasts between these groups were therefore largely independent of the distribution of the sexes. The great majority (87%) of the chronic alcoholics were men and all patients with conversion reactions were women (Table 1). The differences in the sex distribution of these 2 groups did not account for any of the statistically significant differences reported in the tables.

The 5 diagnostic groups differed markedly in their mean ages (Table 1). The manic-depressive patients were the oldest group. Because of the differences already discussed between this group and the other 4, we thought it important to compare these groups on an age-adjusted basis, insofar as this was possible. Each diagnostic group was divided into a younger and older group as indicated in Table 7. The *younger* manic-depressive patients were then compared with the *older* groups in the other 4 diagnostic categories in order to compare diagnostic groups with patients of more nearly equal age.* The

* The fact that the older chronic alcoholic patients were appreciably older than the younger manic-depressive patients did not invalidate this

TABLE 7
DIVISION OF DIAGNOSTIC GROUPS BY AGE

Diagnostic group	Younger patients			Older patients		
	No.	Mean	Age range	No.	Mean	Age range
Manic-depressive depression	7*	41.1	27-47	13	64.0	52-78
Chronic alcoholism	7	30.7	23-39	9*	55.8	44-84
Conversion reaction	7	30.4	17-21	6*	41.7	32-52
Undiagnosed	11	21.4	12-29	10*	35.5	30-42
Sociopathic personality	9	20.7	17-33	7*	26.7	24-34

* These are the groups compared in the text under "Influence of Age and Sex of the Patients."

validity of these comparisons is limited by the small numbers of patients in each diagnostic group when divided according to age and by the fact that the age differences between 2 of the groups was so great that even using this method, older sociopathic personality patients were still significantly younger than the younger manic-depressive patients.

The data presented in Tables 2 through 6 were again compared in these age-adjusted groups. The only noteworthy differences from the original findings were: 1. Only 22% of the older chronic alcoholics and 10% of the older undiagnosed patients gave divorce, separation, or being in jail as a cause for the breaking-up of their parents' homes (see Table 2 for the percentages in the total groups of chronic alcoholic and undiagnosed patients). 2. None of the older undiagnosed patients had been arrested (see Table 3 for comparable figure). 3. The differences in the average duration of jobs among the total groups—manic-depressive longer than the other 4 groups (Table 3)—did not occur in these adjusted groups, except that the sociopathic personality patients still had held a job significantly shorter periods than patients in the other 4 groups. 4. A higher proportion (57%) of the younger manic-depressive patients complained of friction with their spouses than had the total manic-depressive group (see Table 4 for comparable data). These 4 differences do not seriously affect the conclusions previously discussed.

Seriousness of the Suicide Attempt

Another factor that might affect the results of an age-adjusted comparison, since, if the differences in the total groups had been due to differences in the seriousness of the attempt, these differences remained approximately the same

is the relative proportions of patients who had made serious attempts in each diagnostic group. In the chronic alcoholic, sociopathic personality, undiagnosed, and conversion reaction groups there were only 2, 1, 2 and 5 patients, respectively, who had made serious attempts according to our criteria. In the manic-depressive group there were 14 patients whose attempts were judged serious and 6 not-serious. When the serious patients in the manic-depressive group were compared with the not-serious patients, there were no significant differences (within the limitations imposed by the small size of the not-serious group) between them in regard to the factors considered in Tables 2 to 6.

It is of interest that a significantly higher proportion (70%) of the manic-depressive patients had made serious attempts than had the other groups—alcoholics 12%, undiagnosed 10%, sociopathic personality 6%, and conversion reaction 3%. This latter percentage did not quite reach the level of statistical significance when compared with the manic-depressive patients, significance ratio = 1.90).

DISCUSSION

The data of this study show that patients with manic-depressive personality had significantly fewer family adjustment difficulties than the patients with chronic alcoholism, conversion reaction, or sociopathic personality. This was also true of the manic-depressive patients when compared with a group of undiagnosed patients. The majority of patients with a probable diagnosis of chronic alcoholism, conversion reaction, or sociopathic personality. The emotional states of the manic-depressive patients and patients with chronic alcoholism were significantly different from the groups with conversion reaction, sociopathic personality, or undiagnosed patients.

with self, and of worthlessness, whereas those described by the other 4 groups included a high frequency of feelings of anger or spite, of frustration in a marital relationship or in love, and of a desire to gain attention. The manic-depressive patients also showed a significantly better lifelong adjustment than the other 4 groups—a more stable job history, less marital friction, less divorce, less hospitalizations, and fewer arrests. These findings are similar to those reported by Batchelor(2) in discussing the contrast between patients with manic-depressive psychosis and those with sociopathic personality.

The complexity of the relationship between attempted suicide and social stresses is indicated by 3 of the findings of this study. First, although the overall frequency of social difficulties was high in the entire group, there were 2 diagnostic groups, manic-depressive and chronic brain syndrome,⁴ in which the frequency of socially oriented difficulties was relatively low. Four-fifths of the patients with conversion reaction, sociopathic personality, and chronic alcoholism reported a socially oriented disturbance as a precipitating factor in their attempts, whereas only one fifth of the patients with chronic brain syndrome and manic-depressive depression reported socially oriented disturbances. This suggests that the clinical diagnosis is an extremely important intervening variable in determining the importance of socially oriented difficulties in precipitating a suicide attempt.

Secondly, the probable absence of any clinically normal patient in the entire series, implies that when psychiatrically well people are subjected to marital friction, divorce, death of a loved one, financial insecurity, and other social stresses they do not respond by making suicide attempts. This strongly suggests that a suicide attempt is a way of responding to social stress, that is not possible for psychiatrically well persons. This same idea has been expressed in a somewhat different fashion by Stengel(6). "At-

tempted suicide' is a behavior pattern which is at the disposal of only a limited group of personalities." It is still a possibility, however, that psychiatrically well persons may successfully commit suicide.

Thirdly, the question arises whether there is any diagnostic group of psychiatric patients who do not respond by making a suicide attempt, *i.e.*, is there any psychiatric illness in which suicide attempts are rare or never occur as a symptom or response? In this study there was not a single patient with an anxiety reaction (anxiety neurosis). There were other diagnostic categories not found among the patients, *e.g.*, homosexuality or manic phase of a manic-depressive psychosis; however, the relative scarcity of these diseases in the population at large makes it unlikely that they would occur in this series of 109 patients. On the other hand, since anxiety reaction is probably the most prevalent psychiatric illness—about 5% of the entire population(7)—it would be expected to occur in this series of patients. The probable absence of even a single patient with this illness indicates that patients with anxiety reaction do not attempt suicide or do so extremely rarely. Thus, simply being psychiatrically ill is not sufficient to lead to suicide attempts, but suicide attempts seem to occur only in certain specified psychiatric illnesses.

In this connection it is important to ask if any of the 7 undiagnosed patients in whom even a probable diagnosis was not made could have been psychiatrically well prior to their suicide attempt or could have suffered from an anxiety reaction. We have already presented the data indicating that they were probably not clinically well (normal) prior to the attempt. Since even no probable diagnosis was made in these 7 patients, the possibility of any or all of them having had an anxiety reaction cannot be excluded. We think it improbable that they did since every one had at least 2 symptoms not characteristic of anxiety reaction, and none had the fully developed syndrome as described elsewhere(8).

The contrast between manic-depressive patients and the chronic alcoholic, conversion reaction, undiagnosed, and sociopathic personality patients is a contrast between a

⁴ As indicated under "Method" a study of the frequency of patients with chronic brain syndrome was begun during the summer of 1956. These patients represented only a small percentage of the total in respect to the low frequency of socially oriented difficulties.

group of psychotic patients and 4 groups of patients who were not psychotic. Since the psychotic group showed a lesser frequency of socially oriented problems, it is important to ascertain if this was due to incomplete reporting in this group. Dahlgren(4) in a study of attempted suicide has pointed out that data concerning "eliciting causes" of the attempt were generally lacking in his psychotic patients. Since his patients were not systematically interviewed at the time of the attempt, he speculates, in retrospect, that the examiner might have been satisfied with the psychosis as the most important cause of the attempt and did not investigate socially oriented factors. This was not the case in this study because the same social factors were systematically investigated in every patient, regardless of diagnosis. However, even using a standardized questionnaire, it is possible to get less complete answers from patients whose illness interferes with their ability to respond. But none of the manic-depressive patients in this study was mute and only 10% tended to give primarily monosyllabic answers.

A final point about diagnosis is the absence of any patient diagnosed neurotic depressive reaction. As pointed out in the first paper of this series(1), when marked feelings of depression occurred in patients with a pre-existing psychiatric illness such as conversion reaction, chronic alcoholism, or sociopathic personality, the depression was considered a symptom of the pre-existing illness and not as a separate diagnosis. It is possible that the 7 patients in the undiagnosed group in whom a probable diagnosis was not made might be considered by other investigators as examples of neurotic depressive reaction. If this were the case, then patients with a neurotic depressive reaction still would have constituted only 6% of the total group of 109 patients.

Stengel, in an interesting series of papers on attempted suicide(6, 9, 10) has emphasized the "appeal character" and the social effects of the attempt. The long-term social effects of the suicide attempts were not investigated in the present study. Presumably all of the patients in this series who stated they made the attempt in order to gain the attention of a person important in their lives,

some who reported a frustration in love, and some who reported marital difficulties could be considered as having made an appeal. Batchelor, however, has raised the question whether the majority of suicide attempts in sociopathic personality patients in his study had an "appeal character" or were impulsive acts without an element of appeal(2). And, in our own series, very few if any of the attempts of the manic-depressive or chronic brain syndrome patients could be considered to have an appeal character. This interesting concept of the "appeal character" of suicide attempts, therefore, seems to us to require more detailed investigation.

The findings of the present study suggest the following schema for describing the interrelationships of psychiatric diagnosis, social difficulties, and attempted suicide:

1. Psychiatrically well (normal) persons never or very rarely make suicide attempts, regardless of the severity of the social stresses to which they are subjected.
2. Although suicide attempts occur as a mode of response in almost all diagnostic groups in psychiatry, they rarely if ever occur in patients with an anxiety reaction (anxiety neurosis). Apparently patients with anxiety reaction, in spite of being psychiatrically ill, have little predisposition to attempt suicide.
3. Those psychiatric illnesses in which suicide attempts occur may be divided into 2 categories, one (including chronic alcoholism, conversion reaction, and sociopathic personality) in which social difficulties appear to be a frequent precipitating factor for the suicide attempt, and another (including manic-depressive depression and chronic brain syndrome) in which social difficulties are infrequently associated with the suicide attempt. Thus, even in the diagnostic categories in which suicide attempts may occur, there are important differences in the role played by social stresses in precipitating the attempts. It would be interesting to compare systematically patients with chronic alcoholism, conversion reaction, and sociopathic personality who have never attempted suicide, with patients with these illnesses who have attempted suicide, in order to understand what predisposing factors other than social difficulties and clinical diagnosis

are necessary to precipitate a suicide attempt in these groups of patients.

SUMMARY

1. A study has been reported of social factors in the suicide attempts of 109 patients brought to a general hospital immediately after having made a suicide attempt.

2. Patients with chronic alcoholism, conversion reaction, and sociopathic personality reported a much higher frequency of social difficulties, such as marital friction, divorce, job instability, and financial dependency, than did patients with manic-depressive psychosis and chronic brain syndromes. They not only were involved in more social difficulties at the time they made the suicide attempt, but also reported more such difficulties throughout their lives.

3. Just before the manic-depressive and chronic brain syndrome patients attempted suicide they were disturbed by feelings of depression, self-disgust, and worthlessness, but seldom by feelings of anger or spite towards other persons or by feelings of frustration or neglect caused by others, while the patients in the other 3 diagnostic groups showed the opposite pattern.

4. There were probably no psychiatrically well patients and probably no patients with an anxiety reaction (anxiety neurosis) in the entire group of 109 patients who had made a suicide attempt.

5. The interrelationships of social difficulties, diagnosis, and suicide attempt, based on the findings of this study, were discussed.

BROMIDE INTOXICATION AND QUANTITATIVE DETERMINATION IN SERUM

SIDNEY J. TILLIM, M. D.¹

Finding in a patient a blood bromide of 1470 mgm %, reaffirmed in another laboratory, prompted an inquiry to Queries and Minor Notes of the Journal of the American Medical Association. The consultant's reply(1) pointed out the unreliability of the Wuth method for quantitative determinations. It also stated, "By all the evidence with which I am familiar, blood bromide level of 1470 mgm % not only exceeds any published records, but in my judgment it is quite impossible since it far exceeds the amount compatible with life . . . and must be explained by possible error in calculation or computation."

WUTH METHOD

The Wuth method with various modifications has been used almost exclusively in clinical laboratories for approximately 30 years. In essence, it consists of adding gold chloride to a protein-free sample to be tested. Changing color to yellow, brown or even reddish brown indicates the presence of bromide, presumably due to formation of gold bromide. The percentage concentration is determined with a colorimeter. Wuth originally used the less accurate method of comparator tubes.

The author does not recall any previous publication of blood bromide values even approximating that found in the patient. The librarian of the American Medical Association(2) after a search located a reprint of an article by Gundry(3) which mentions values of 555 and 715 mgm %. It also refers to 7 deaths or about 1% of bromism cases reported in the literature. Dr. Maurice J. Taylor(4), Salt Lake City, who had previous experience with our patient reported February 10, 1955, that in the past 18 months he had found 2 cases with blood bromide levels of 960 and 1350 mgm %, "still apparently able to work but having evidence of personality changes." One of these 2 patients had an exploratory for sus-

pected cord tumor at T3 with a finding of "generalized arachnoiditis apparently due to bromine changes."

The AMA consultant volunteered the opinion that "bromides are relatively mild and relatively harmless unless taken to excess over long periods of time." This is a more mild caution about the use of bromides than appears in the advertising of Miles Nervine which happens to be the product the patient had taken. The manufacturer cautions that "over dosage or habitual use, or use in the presence of kidney disease may be dangerous." The author has directed attention to some of the hazards of bromide medication(5). Neither the reassurance nor the caution contributes to public protection. Well persons do not require sedatives. Bromide users are not dependable to limit use to mild conditions while the drug is purchasable over the counter. There are definite contraindications to the use of bromides which physicians sometimes overlook with detriment to patients. Miles Laboratories questions the authenticity of reported cases of bromism with the statement "most of such cases in a medical history sense are quite unreliable(6)." This minimizes the incidence and seriousness of the problem. The clinical picture of bromism in toxic degree is sufficiently suggestive and the course under treatment is conclusive. Treatment of the bromism is the primary therapeutic goal; underlying conditions such as nutritional disturbances, organic disease and psychic problems are dealt with afterward. Our cases support these views.

CASE REPORTS

CASE 1.—D.C., a 45-year-old periodic alcoholic, admitted January 12, 1955, after several admissions to 2 different hospitals since November 2, 1954, when first admitted as a case of acute alcoholism. His last discharge from the general hospital was January 2 with a supply of paraldehyde to complete his recovery. On January 5 the paraldehyde was discarded in favor of "Nervine" because the wife protested the odor around the house. Between

¹ Address: Nevada State Hospital, Reno, Nevada.

then and the date of admission he consumed about 20 oz. of this preparation. Commitment as a mental case was based on episodes of confusion and disorientation, agitation, restlessness, insomnia and intermittent voicing of paranoid delusions. Physical examinations showed tremors of the hands, slurring speech and an ataxic gait. A blood bromide determination on January 13 was reported as 1470 mgm %. Because of the unusual finding, the laboratory repeated the test several times with various modifications and the lowest figure that day was 1438 mgm %. The laboratory used the modified Wuth method and the Klett-Somerson Colorimeter according to the Klett-Somerson clinical manual. Separate samples were submitted the following day to another laboratory. The results of tests in the two laboratories follow:

Laboratory 1			
1/13	Serum	1470	
	4 hrs. later	1438	
1/17	Serum	916	
	Urine	460	
1/20	Serum	601	
	Urine	517	
1/27	Serum	297	
	Urine	428	
2/2	Serum	114	
2/9	Serum	49	
Laboratory 2			
1/14	Serum	1250	
	Spinal fluid	954	
	Urine	562	
1/17	Serum	966	
	Urine	377	
1/20	Serum	722	
	Urine	461	

Subject was treated with oral and intravenous chlorides. Sedation was provided from chlorpromazine of only 25 mgm t.i.d., except for the first dose of 50 mgms. There was a temporary aggravation of the neuropsychiatric symptoms during the 3rd and 4th days in the hospital, but steady progress toward recovery thereafter. Blood bromide dropped to 49.2 mgm % on February 9 and patient was discharged as recovered.

CASE 2.—A.G., a 74-year-old white male, admitted November 9, 1954, was well until about 2 months before admission. He became depressed and agitated over the alleged loss of a mining claim and was admitted to a private sanitarium. There he received 8 electroshock treatments while residing outside. At the time, he received Thorazine medication. He improved clinically, but developed jaundice, presumably due to the medication. He also received a prescription of Sedaphen, a mixture of phenobarbital and bromide, to take one or two teaspoonfuls "as needed for nervousness," from October 7 to the 24. On his return home November 7 he was on paraldehyde for 3 days, drams

2, "as needed," until admitted to this hospital. On admission, he was in a restless, stuporous delirium. Physical examination was difficult because of uncooperativeness. He failed to improve on general supportive measures. The atypical character of the psychosis led to closer questioning of the relatives about previous medications and a blood bromide determination done November 18 showed a level of 323.3 mgm %. The spinal fluid bromide on November 22 was 103.3 mgm %. Subject continued disturbed and uncooperative, making administration of chlorides, either oral or by vein, not too satisfactory.

Ten days post-admission he showed signs of cardiac decompensation and elevation of temperature. On November 22, he was transferred to a general hospital and there died December 11, 1954. Causes of death were given as: 1. Organic heart disease; 2. Bromide intoxication. Blood bromides taken at the general hospital showed on November 23 a concentration of 222 mgm %, and on December 9, 172 mgm %.

CASE 3.—F.S., a 79-year-old married Italian, was admitted January 14, 1953 because of recurring episodes of confusion. The last episode began 2 weeks before admission and was associated with auditory and visual hallucinations. He was a transfer under commitment from a general hospital where he had been treated for 5 days with phenobarbital and dilantin for tremors and convulsive reactions. Examination showed general tremulousness, confusion, disorientation and hallucinosis. The heart was enlarged in mild decompensation with auricular fibrillation and liver enlargement. He walked unsteadily on a wide base. He had been on Elixir Chloral and Bromide which contains 120 grains of bromide per ounce from December 10 to the 24, consuming 10 to 12 ounces before being hospitalized. The prescription instructions were for a teaspoonful t.i.d. and 2 teaspoonfuls at bed time. A blood bromide determination the day after admission showed 304.2 mgm %. The second test on January 22 showed 299.7 mgm %. On January 23 the spinal fluid bromide was 183.15 mgm %. The patient made gradual improvement under chloride therapy and on February 6, 1953 was returned to the general hospital for treatment of his cardio-renal syndrome. He was readmitted May 12, 1953 and died June 14, 1953 of myocardial failure.

CASE 4.—R.C., a 37-year-old chronic alcoholic in his third admission was brought to the hospital January 28, 1954 from the local jail. He had been charged with drunkenness. Physical examination was essentially negative except for a generalized punctate rash over the chest, abdomen and thighs. He was oriented and co-operative but boastful and garrulous.

During the 3 days in jail he received bromide medication, prescribed by a physician but dispensed by the jailer so that the amount given is uncertain. A blood bromide determination the day after admission revealed 274.28 mgm %. A second examination 4 days later showed a blood bromide level of 260.75 mgm %. Sodium chloride therapy reduced

the blood bromide level to 105.45 mgm % by the twelfth day. Recovery was uneventful including disappearance of the rash.

CASE 5.—S.G., a 62-year-old white female, was admitted June 13, 1955 as a transfer from a local general hospital where she was admitted for an acute emotional disturbance, due to the impression that the neighbors had read a telegram of her son's accidental death, which was true. A daughter related that the patient had been paranoid for 8 years and had become worse the past 2 weeks. She had been on "Nervine" for 6 months—the amount taken is not known. Physical examination showed her unable to stand or walk with her eyes closed and ataxia with eyes open. There was a tremor of the tongue and lips. Pupils were contracted and did not react to light or accommodation. Deep tendon reflexes were depressed or absent. She expressed delusions and was disoriented for time and place. A bromide determination June 14, 1955 showed 228.7 mgm % for the blood and 199.8 mgm % for the urine.

Patient made uneventful progress in treatment with chlorides. Six days after admission the bromide level had dropped to 114.75 mgm % for blood and 58.8 mgm % for urine.

The patient was discharged as recovered from the acute psychosis on July 7, 1955. Diagnosis—psychosis, bromide intoxication and paranoid personality.

DISCUSSION

Studies by Gray and Moore(7) justify the assumption of error in the laboratory findings of Case 1, but not the assumption of "possible error in calculation or computation(1)." The samples were run in 2 commercial clinical laboratories, staffed by competent personnel. A patent fault or source of possible error in a laboratory method should appear as a definite percentage incidence. This is not evident from the literature. Their studies seemed only concerned with moderate concentrations and not the extreme of our case and the few others mentioned. Some significance should attach to the rate of reduction, percentage-wise, which roughly corresponds to experience with lesser concentrations. The tests were done in the same laboratories. Physiologic or chemical factors influencing the first specimen probably would not persist for a week in multiple samples. It should be noted further that there was the expected ratio between blood and spinal fluid values. Dr. Compton(6) claims the Wuth method "wholly unreliable" for values over 300 mgm %. He recommends the Brodie-Friedman method (J. Biol.

Chem., 124:511, 1938) which is allegedly too complex for routine in clinical laboratories. Is it possible that the consumption of an inordinate quantity of bromides in a relatively short time can produce in humans such a concentration in serum without irreversible organic damage?

Our patient consumed in uneven daily amounts for 7 days approximately 8 times the daily therapeutic dose of bromides. Credence is added to these speculations by the fact that 8 months previously the same person had more serious neurological complications with a blood bromide of 100 mgm %. At that time the disability advanced over several months. There was then suggestive evidence of multiple-sclerosis and posterolateral involvement. The neurologic findings were "marked ataxia, weakness, past pointing, blurring speech, hyperactive K.J's. and loss of vibration sense in both legs(2)." He had been on combinations of barbiturates and triple bromides. The effectiveness of chlorpromazine in this case is worth noting. Generally the treatment for alcoholic withdrawal is no mean task—from the so-called "comprehensive" approach tantamount to nearly everything in the pharmacopoeia, chief reliance on paraldehyde(8, 9,) the vitamin "cocktail" with insulin, and hypoglycemic therapy preferred by the author(10). Effectiveness of Thorazine reduced the need even for the latter procedure. Dosage beyond the first was relatively small.

Cases 2 and 3 are presented because of fatal outcomes. Their immediate causes of death do not indicate the bromide factor but no reasonable consideration can exclude its contribution. In case 2 the man was in good health 3 months previous to his death. Much happened to him by way of treatment which could be implicated, such as the electroshock. The delayed bromide elimination probably affected adversely the course of his illness. He had a higher bromide concentration than the first test indicated because no bromides were administered at the hospital. Combined use of electroshock and sedatives, particularly Thorazine, is not recommended.

Case 3 illustrates the often repeated caution to beware of bromides for elderly persons, especially in the presence of cardiac or renal involvement. This man took the

bromides on prescription. Already handicapped by recurring episodes of confusion, bromides would tend to excite delirium. It is not surprising that his behavior deteriorated on the medication in the general hospital where the bromism was not suspected. The accumulative action was rapid and the elimination characteristically slow. An aggravation of the cardio-renal syndrome may be assumed.

Case 4 shows the rapidity with which symptoms of bromism may develop. In 3 days under "controlled" (jail) conditions, he developed signs of intoxication and a blood concentration of 274.28 mgm %. Such rapidity of development is not generally recognized. The rash which occurs in about 10% of cases does not necessarily follow prolonged use. It may result from irritation, when bromide is eliminated through the skin, or an allergic reaction. Case 5 shows an accentuation of a psychotic syndrome. This, too, is a well recognized possibility against which physicians should guard. The promptness of recovery from the intoxication syndrome identifies the offending agent. She has been out of the hospital 14 months.

Gray and Moore(7), besides finding all tests short in accuracy, advise "it is better to determine blood and urine chlorides for which several exact methods exist. . . . The resulting chloride deficiency is probably more importantly the cause of the symptoms of the nervous system and skin disturbances than is the increase in bromine in the blood." They cite approvingly Minaki and Gillen(11) that "there is no correlation between the bromide level and the mental state." Individual tolerances for other drugs and alcohol are well known. They claim a chloride replacement of 40% or over would be fatal, while 25 to 36% cause only intoxication. Unfortunately no chloride determinations were done in Case 1. Campbell(8) explodes the popular assumption of a correlation between blood bromide level and psychiatric manifestations, that 150 mgm % is the dividing line. He cites a patient with 50 mgm % blood bromide who was retarded, drowsy, partially disoriented with hyperreflexia, slurred speech and nystagmus. He also notes that 32 of his 36 cases had major neuropsychiatric disturbances underlying the

intoxication. Barbour(12) claims "the blood bromide level will vary with the renal efficiency and with the fluid intake." The blood bromide level at which neuropsychiatric symptoms appear depends also on the underlying psychic disturbance for which the drug was taken.

TREATMENT

Bromism is not difficult to treat successfully. The treatment may be differentiated into 3 phases: sedation with a minimal of physical restraints; elimination of the bromide by chloride substitution; and meeting of nutritional requirements.

Sedation for a delirious patient presents special problems. Paraldehyde has been suggested as the drug of choice(8, 9). This seems a poor choice because paraldehyde tends to aggravate delirium as observed in cases of alcohol withdrawal. Barbiturates are no better. The author has used hypoglycemic reactions with considerable effectiveness(5). This method has these advantages: encourages fluid intake which may incorporate sodium chloride, stimulates hunger and acceptance of food, and after each treatment temporarily improves mental clarity. Elimination of the bromide may be increased through the urine output and through the skin, if copious diaphoresis is induced.

Harris and Derian(13) report rapid clearing of symptoms with the use of niacinamide in daily amounts of 600 to 750 mgms. They consider this treatment particularly useful in cases with cardiac involvement when ammonium chloride should be substituted for the sodium chloride. Ataraxics are a promising means of sedation. Thorazine was obviously effective in Case 1, in the face of failure in the general hospitals with paraldehyde, barbiturates and opiates.

Replacement of bromides with chlorides, usually sodium chloride, is a specific treatment. However, this is subject to modifications dependent upon requirements of individual cases, for example, the substitution of ammonium chloride for persons with a cardiac deficit. The presence of nausea may preclude either form of chloride by mouth, to be circumvented with sodium chloride intravenously. The suggested use of niacinamide

as a means of improving mental status merits further trial. Addition of mercurhydrin to the sodium chloride treatment allegedly enhances the output of bromide through the kidneys by 60%, and 130% when ammonium chloride is used(9). Evans(14) reports a very large increase in kidney excretion of total halides when mercurial diuretics are used, with a proportionate increase in the excretion of bromides. Further study on the use of mercurials should not be tried on patients with renal involvement. Cornbleet(15) prefers ammonium chloride even in the absence of cardiac complications, but ammonium chloride in adequate amounts is prone to produce gastric distress. Nutrition *per se* is not a serious matter. Malnutrition is less frequent with bromism than with alcoholism, unless the intoxication existed for a considerable time.

SUMMARY

Five cases were presented illustrating several principles for the prescribing of bromide medication. A case is reported of an unprecedented serum bromide value as determined by the modified Wuth method. The suggestions that very high bromide findings are erroneous warrant further controlled studies. A few reports of similar findings are not conclusive for condemnation of a method in use for 30 years. Physicians and

druggists still need warning against indiscriminate dispensing of bromides. Bromides may be mild but not harmless—they are usually taken by persons incapable of exercising good judgment or moderation. Dispensing without a physician's prescription should be prohibited.

TWO-YEAR FATE STUDY OF THORAZINE-TREATED PATIENTS

PAUL E. FELDMAN, M.D.¹

Ample literature is now available reporting upon the efficacy of short-term treatment with Thorazine.² Both favorable as well as unfavorable reports have been assessed upon the basis of information obtained following the administration of Thorazine for 2 or more months. Because of the interest in ataraxics, these short-term observations were both practical and desirable.

Sufficient time has now elapsed since the introduction of Thorazine (early in 1954) to observe its effects after it has been administered for 2 or more years. These observations should provide additional information as well as support or disproof of certain predictions which were made a year or two ago. Most clinicians and researchers in this field have been awaiting answers to such questions as—Does tolerance formation follow the prolonged administration of Thorazine? Can dosages be reduced to any substantial degree after maximal therapeutic responses are obtained? Is there evidence of continued toxicity? Do side effects persist with the same intensity and frequency as observed early in medication? If they do persist, how are they managed? Is there evidence to support Bailey's(1) warning that the ataractic drugs are poisons? What portion of chronic psychotics respond to Thorazine to the degree that they can be released from the hospital? What has been the fate of those patients who responded favorably and were released a year ago? How many of them have had to return to the hospital? Why? What has been the fate of those who did not respond to a degree where release from the hospital was feasible? Are they still receiving Thorazine? If not, why not?

METHOD

In a controlled research study, 317 patients at the Topeka State Hospital were

¹ Director of Research and Education, Topeka State Hospital, Topeka, Kan.

² Thorazine for this study provided by Smith, Kline and French Laboratories.

FIG. 1

placed upon Thorazine medication during June 1954. Accurate records of these patients have been maintained and, following one year of medication, the analysis of our results was published(2). At that time it was reported that 41 of these patients had been released from the hospital. This first year report also gives the details of the criteria used in the evaluation of the patients. A similar method of evaluation was used for the 2-year report.

RESULTS

Fig. 1 indicates the fate of the 317 patients who comprise the test group.

RELEASED-GROUP

Table 1 indicates the number of patients released as of July 1, 1956 and a comparison

TABLE 1

TWO-YEAR RELEASE RATES

	Patients discharged or paroled *	
	After 1 year	After 2 years
Number of patients.....	32	85
Percent of total group**..	10.1	28.0
Average age	45 yrs.	47 yrs.
Average duration of illness..	5 yrs.	6+ yrs.

* Does not include patients re-hospitalized from parole.

** Does not include patients who died.

with the group released a year prior to that time.

Table 2 contrasts the composition of the first and second year released-groups.

The 41 patients who on July 1, 1955 comprised the first year released-group underwent the following fate by July 1, 1956:

Discharged from parole.....	18
Still on parole.....	14
Died	1
Returned to hospital.....	8

Five of the 8 patients in this group who were returned to the hospital had failed to continue medication after their release.

At the end of the second year, 99 patients who were no longer in the hospital showed the following fate:

Discharged from parole..	36	} 83
Still on parole	47	
Died	14	
Elopement	2	

A questionnaire sent to the 83 patients on parole or discharged, yielded the following information (60 patients responding); Patients still continuing on Thorazine: 40 (66.6% of released group); Average maintenance dose of Thorazine: 125 mg/day. Of the 20 patients no longer receiving Thorazine, 18 discontinued the drug at the time of release from the hospital and have not found it necessary to resume this medication. The remaining 2 patients have

changed to some other type of medication upon the prescription of their family physician.

IN-PATIENT GROUP

Two-hundred-twenty of the patients are still hospitalized; and of these, 144 (65.5%) are still receiving Thorazine. Of this latter group, 21 patients (14.6%) are receiving dosages greater than were administered a year ago, an average increase of 225 mg/day.

Thirty-seven patients (25.7%) are receiving the same dosages as administered the year before, and 86 patients (59.8%) are receiving smaller dosages than a year ago—an average decrease of 375 mg/day.

The latter 2 groups—those receiving identical and decreased dosages, represent 85.4% of the patients who are now receiving Thorazine. Twelve additional patients have continued with Thorazine medication, but this has been combined with another ataractic drug (Reserpine, Frenquel or Pacatal).

Eighteen of the patients whose Thorazine medication had been discontinued are now receiving some other ataractic drug with a more effective response.

During the past 2 years, 11 patients in the group have been returned from parole. The time outside the hospital varied from 2 weeks to 10 months and no consistent cause for return is apparent. Four were returned for inability to maintain improvement gained in

the hospital, 2 for inability to adjust in the community, and the remaining 5 for "reasons not stated."

IMPROVEMENT

A survey of the present behavioral responses of those still receiving Thorazine, following the criteria for evaluation used a year ago(2), indicates that Thorazine remains effective in the same areas as noted previously.

Since a non-technical evaluation can be quite revealing, the following question was presented to the charge aide of each patient: "How do you feel patient X is getting along now?" No prompting or instructions were added which might bias their responses. The responses showed equally favorable or unfavorable impressions. The following are some of the typical replies:

Patients no longer receiving Thorazine

- "About the same."
- "Disturbed most of the time."
- "Slow—no energy."
- "Kind of backward and forward."
- "Fluctuates—not so good."
- "Now better than ever."
- "Fairly well."
- "O.K.—does work."
- "Doing fine."
- "Fine without medication."
- "Fine—works for Dr S."

SIDE EFFECTS

Table 3 indicates the incidence of side effects on the in-patient population. It was not feasible to include data from outpatients because of the unreliability of objective evaluations by lay observers. Drowsiness still appears to be the most common side effect and apparently increases in frequency with the continued use of Thorazine. However, only one-third of the cases of drowsiness reported were of such severity as to warrant antidote medication. In this latter respect, small doses of dextro-amphetamine or ephedrine sulphate effectively masked this symptom.

Parkinsonism appears to have doubled in frequency. In cases in which the muscular rigidity, excessive salivation or hyperkinetic phenomena were excessive, the syndrome

Patients still receiving Thorazine

- "About the same."
- "Not so good."
- "Is fairly loud—hallucinates."
- "Still very hyperactive."
- "I can't see any difference in her"
- "Little better."
- "Much, much better."
- "Just fine—works every day down town."

TABLE 3
INCIDENCE OF SIDE EFFECTS OF HOSPITALIZED PATIENTS

Side effect	Percentage of patients showing side effects	
	1954-55	1955-56
Drowsiness	23	39.0*
Parkinsonism	3.8	6.6
Allergy	3.8	2.9
Dizziness	2.8	4.4
Hypotension	2.8	2.9
Depression	2.2	2.2
Jaundice	1.9	0.7
Blood changes	1.9	2.2
G. I. disturbances	1.9	4.4
Turbulence	1.9	4.4
Seizures	0.9	0
Edema	0.9	0
Visual disturbances	0.6	0

* Drowsiness reported in 53 patients, but in only 17 patients (32%) was the drowsiness of severity to warrant antidote medication.

was effectively curbed by the administration of Cogentin or Artane.

Skin rashes were the only allergic phenomena noted. They occur in nursing personnel handling pulverized Thorazine tablets as well as in patients. These rashes are effectively controlled by Benadryl, Teldrin, Chlortrimeton, or Hydrocortone Lotion.

Dizziness, though occurring at almost doubled frequency, was extremely mild and did not require any special medication.

Hypotension occurs at an unchanged frequency, but is very mild and never incapacitating. It can be counteracted by small doses of ephedrine sulphate.

Depression is reported in 2.2% of cases. It was mild and responded well to dextro-amphetamine.

One case of jaundice is reported; it subsided uneventfully without discontinuation of medication and its relationship to Thorazine is unclear. The relatively low incidence of jaundice at the 2-year mark is in keeping with the concept that the obstructive hepatitis seen in these patients is probably allergic in nature and similar in mechanism to the Herxheimer Reaction noted following arsenical medication.

Three cases of blood changes were reported with all 3 cases showing WBC counts in the 2,000-3,000 range. Thorazine was discontinued in these patients and recovery was uneventful.

The most common gastro-intestinal disturbance was constipation which responded well to mild laxatives. Occasionally emesis was reported.

Turbulence continues to manifest itself and was reported 3 times as often as a year ago. It appears to be related to dosage-manipulations—up or down. Convulsive seizures, visual disturbances, urinary retention and incontinence were not reported.

SUMMARY AND CONCLUSIONS

1. Ninety-six chronically psychotic patients (26.2%) treated over a 2-year period with Thorazine have been released from the hospital. The stability of the release is indicated by the fact that only 11 of these patients have been returned from parole.

2. Younger schizophrenics are more likely to respond to Thorazine to the extent that their release from the hospital is feasible.

3. Of the patients remaining in the hospital, 65.5% are still receiving Thorazine.

4. Behavioral improvement following Thorazine medication is maintained for at least 2 years.

5. There appears to be evidence that prolonged administration of Thorazine does *not* lead to tolerance formation. Eighty-five point four per cent of the patients are receiving identical or smaller dosages of Thorazine than they were receiving a year ago.

6. Some patients who responded minimally to Thorazine have shown a better response to one of the other tranquilizers.

7. Eighteen of the Thorazine patients are showing a better response to combined therapy.

8. Nursing personnel express conflicting opinions as to the efficacy of Thorazine medication.

9. There is ample evidence of continued toxicity of Thorazine after 2 years of medication. This reinforces the concept that ataractic therapy must at all times be under medical supervision.

10. Maintenance dosages are substantially smaller than the dosages necessary to obtain the initial therapeutic response.

11. Blood studies (at monthly intervals) must be continued so long as the patient receives Thorazine.

12. The need for routine liver-function tests is equivocal unless Thorazine medication is interrupted and then restarted.

13. Side effects persist throughout the period of medication. All of them can be controlled, ameliorated or eliminated by the administration of proper antidote or discontinuation of Thorazine medication.

THE INTRAFAMILIAL ENVIRONMENT OF SCHIZOPHRENIC PATIENTS: II. MARITAL SCHISM AND MARITAL SKEW

THEODORE LIDZ, M.D., ALICE R. CORNELISON, M.S.S., STEPHEN FLECK, M.D., AND DOROTHY TERRY, Ph.D.¹

We are engaged in a long-term intensive study of the intrafamilial environment in which the schizophrenic patient grows up.² Space does not permit an adequate exposition of the theoretic framework behind these investigations, and we shall seek to impart only an indication of our orientation. Previous studies have indicated that serious pathology of the family environment is the most consistent finding pertaining to the etiology of schizophrenia. We are considering schizophrenia as an extreme form of a social withdrawal, specifically characterized by efforts to modify reality into a tenable form by distorting the symbolization of reality, or through extreme limitation of the interpersonal environment. A theory of schizophrenia must explain both the patient's need to withdraw regressively and symbolically from the realm of shared living and meanings, and also his ability to do so. As the family is the primary teacher of social interaction and emotional reactivity, it appears essential to scrutinize it exhaustively. There is now considerable evidence that the schizophrenic's family can foster paralogic ideation, untenable emotional needs, and frequently offers contradictory models for identification which cannot be integrated. The importance of the very early mother-child relationship seems clear, but we are tentatively considering that deficiencies in this relationship may only establish a necessary *anlage* for the development of schizophrenia—or for certain other psychiatric and psychosomatic disorders. An *anlage* is not a cause. It remains possible that specific determinants may be found in the later difficulties in interpersonal relationships. We hypothesize that the ego weakness of the schizophrenic may be related to the introjection of parental weakness noted in the

mother's dependency upon the child for fulfillment; to the introjection of parental rejection of the child in the process of early identification with a parent; and to the depreciated images for identification presented by the devaluation of one parent by the other.

The careful collection of data from 16 families has now continued for several years, through weekly interviews with family members; observation of their interaction with each other and the staff; visits to the home, by projective testing, and other techniques. The methodologic problems in collecting and assessing data are many, but technical difficulties cannot continue to bar exploration of an area which appears vital to the study of schizophrenics.

It is important to point out that the families studied are middle and upper class, able and willing to maintain a patient in a private psychiatric hospital for a long period. The only criteria for inclusion in the study are relative youth of the patient, hospitalization in the Yale Psychiatric Institute, and that the mother and at least one sibling are available as informants. By comparison with other groups, it has become quite certain that there is a bias toward the selection of better organized families of schizophrenics rather than toward the more disorganized.

The material which is being collected is complex and its analysis is difficult and time consuming. A year ago we reported briefly our initial survey of the fathers in 12 of these families (7) calling attention to the serious psychopathology found in the fathers of schizophrenic patients, which had previously been generally neglected because of the focussing of attention upon the early mother-child relationship and the pathology of the mothers. Today we report briefly on another fragment of the work in progress, namely on the defects in the marital relations of parents of schizophrenic patients. The topic is selected because, like the psychopathology of the fathers and mothers, the marital difficul-

¹ From the Dept. of Psychiatry, Yale Univ. School of Medicine, New Haven, Conn.

² This project is supported by grants from the National Inst. of Mental Health.

ties stand out in bold relief; and also because these marital problems are basic to the study of the intrafamilial milieu. The potential relationship of these parental difficulties to the maldevelopment of the children will have to remain largely implicit in this paper.

From past experience, we know that we must emphasize as strongly as possible that we do not seek to establish a direct etiologic relationship between marital discord between parents and the appearance of schizophrenia in an offspring. It is obvious that bad marriages do not, in themselves, produce schizophrenic children. The presentation is simply one of a series of efforts to convey various facets of the family environment as they become apparent in our study. It is not a matter of conjecture but observation, amply documented, and it is unlikely that it does not have some relevance to the problem of schizophrenia.

The deficiencies in the relationships between parents of schizophrenic patients have been noted and studied by relatively few investigators. Lidz and Lidz(6), in 1949, called attention to the frequency of broken homes, markedly unstable parents, and unusual patterns of child rearing, and found that at least 61% of 33 patients had come from homes marked by strife. Tietze(12), in 1949, reported that 13 of 25 mothers of schizophrenic patients reported that their marriages were very unhappy but that the statements by 9 that their marriages were "perfect" did not stand up under investigation, for the marriages were strained and far from happy. Helen Frazee(3), in 1953, found that 14 of 23 parental couples were in severe conflict and none was "normal" or had "only moderate conflict," whereas 13 of the control parental couples were near normal or showed only moderate conflict. None of the parents of schizophrenic patients revealed any degree of marital stability, whereas well over one-half of the control group manifested only moderate conflict or had made a good marital adjustment. Gerard and Siegel(4) (1950) found open discord between 87% of the parents of 71 male schizophrenics as against 13% in the controls. Reichard and Tillman(10) cite the unhappy marriages of the parents of schizophrenics and analyze the

sources of discord in terms of parental personalities. Of interest, too, is Murphy's report(8) (1952) of the family environment of 2 adopted children who became schizophrenic, in which the marital relationship was filled with hostility and mutual recrimination between two seriously disturbed parents. Many individual case reports emphasize or mention the bad marital relationship between the parents.

In our efforts to study and describe marital relationships, it has become apparent—as it has to others—that one cannot adequately describe a family or even a marriage in terms of the personalities of each member alone. A family is a group and requires description in terms of group dynamics and the interaction among its members. We are indebted to Parsons and Bales and their co-workers(9); to J. Spiegel and F. Kluckhohn(11); Nathan Ackerman(1); Reuben Hill and his co-workers(5); Bradley Buell and the Community Research Associates(2), and others for their efforts to analyze marital and family interrelationships. We are still searching for suitable frames of reference, but the deficiencies of descriptive method should not blur the basic consideration—that the parental relations are highly disturbed in all of the 14 cases whose study is nearly finished, as well as those which are still incomplete.

The requisites for successful marriages are unfortunately far from clear, but some essentials are emerging. A couple must find reciprocal interrelating roles with each other and in their respective roles with their children. Absence of such role reciprocity means making constant decisions, self-consciousness and tension. As Spiegel(11) has pointed out, role reciprocity requires common understanding and acceptance of each other's roles, goals and motivations, and a reasonable sharing of cultural value orientation. Mutual trust and effective communication between partners are important requisites given effect by support of the spouse's role and self-esteem during periods of loss of confidence. We have been particularly impressed by the need to maintain lines between generations: **that is, not to confuse or blur distinctions between parents and children.** Spouses cannot remain primarily in a dependent position to

their parents to the exclusion of an interdependent marital relationship; nor can one behave primarily as the other's child; nor as a rival with one's own children for the spouse's attention, nor reject a parental role completely (9). The need for both parents to form sources of primary love relationships for children and objects for stable identification will not be entered upon here, as we are concerned primarily with marital interaction.

It seems helpful to follow the lead of Parsons and Bales (9) and consider the father's role in the family as primarily "adaptive-instrumental" and the mother's as "integrative-expressive." In broad terms, which may differ somewhat from Parsons', the father supports the family, establishes its position with respect to other families, determines prestige, and the social patterns of interaction with other groups. The mother's basic functions pertain to intrafamilial interactions; tensions and their regulation; supplying the oral needs, both tangible and affectional. Each parent, in addition to filling his own role, must support the role of the other through his or her prestige, power, and emotional value to other family members.

The marriages of these parents of schizophrenics are beset by a wide variety of problems and ways of adjusting to them. However, the 14 marriages can be placed in 2 general groupings, which, of course, tend to overlap in places. Eight of the 14 couples have lived in a state of severe chronic disequilibrium and discord, which we are calling marital schism. This paper will focus primarily upon these 8 couples. The other 6 couples have achieved some state of relative equilibrium, in which the continuation of the marriage was not constantly threatened; and the marital relationship could yield some gratification of needs to one or both partners. However, the achievement of parental satisfaction or the sacrifices of one parent to maintain marital harmony resulted in a distorted family environment for the children.

MARITAL SCHISM

In the 8 families in which the state of disequilibrium designated as marital schism existed, both spouses were caught up in their own personality difficulties, which were ag-

gravated to the point of desperation by the marital relationship. There was chronic failure to achieve complementarity of purpose or role reciprocity. Neither gained support of emotional needs from the other; one sought to coerce the other to conform to his or her expectations or standards, but was met by open or covert defiance. These marriages are replete with recurrent threats of separation, which are not overcome by efforts at re-equilibration, but through postponement of coming to grips with the conflict or through emotional withdrawal from one another—but without hope or prospect of improvement or ever finding any gratification in the marriage. Communication consists primarily of coercive efforts and defiance, or of efforts to mask the defiance to avoid fighting. There is little or no sharing of problems or satisfactions. Each spouse pursues his needs or objectives, largely ignoring the needs of the other, infuriating the partner and increasing ill-will and suspiciousness. A particularly malignant feature in these marriages is the chronic "undercutting" of the worth of one partner to the children by the other. The tendency to compete for the children's loyalty and affection is prominent; at times to gain a substitute to replace the affection missing from the spouse, but at times perhaps simply to hurt and spite the marital partner. Absence of any positive satisfaction from the marital relationship (excluding the children) is striking, though strong dependency needs may be gratified in a masochistic fashion in a few instances. Mutual distrust of motivations is the rule and varies only in the degree with which realistic causes for mistrust extend into the paranoid.

In 7 of these 8 families, the husband retains little prestige in the home and with the children, either because of his own behavior or his wife's attitudes toward him. He becomes an outsider or a secondary figure who cannot assert his instrumental leadership, and when he strives to dominate in tyrannical fashion, he eventually forces the family to conspire to circumvent him. His instrumental role is basically limited to financial support, which he may have originally considered as a husband's basic function, or he is relegated to this position. The ineffectual

role of the father applies equally to 5 of the 6 marriages in the other group in which marked schism is not present.

The wives will be considered only in respect to their wifely functions, excluding the complex maternal relationships which also cause marital discord because eccentric, cold, rigid, or over-indulgent attitudes toward the children antagonized the husband. All distrusted their husbands and had no confidence in them. They were openly defiant in major areas of interaction and rather habitually disregarded or circumvented their husbands' demands. They were emotionally cold and distant and, with one or two exceptions, sexually aloof. They competed for the attention and affection of the children and tried to instill their value systems, which differed from those of their husbands.

Communication in these marriages is greatly impeded by mutual withdrawal and by masking of motives from one another, but is further hindered because 4 wives show seriously scattered thinking and 4 husbands show paranoid thinking and rigidity. The imperviousness to the feelings of others, characteristic of many parents of schizophrenics, also creates communicative difficulties.

It seems of interest that in 5 of the 8 marriages, the focus of the partners' loyalties remained in their parental homes, preventing the formation of a nuclear family in which the center of gravity rests in the home. The grandparents or the parental siblings often carried out much of the expressive and instrumental roles rather than the marital partners. The cardinal emotional attachment and dependency of one or both partners remained fixed to a parental figure and could not be transferred to the spouse.

The 8 families can be grouped into 3 categories, according to the groupings of the Community Research Associates in their "Classification of Disorganized Families," which describes 10 combinations of masculine and feminine personalities which are potentially hazardous to successful marital and family relationships(2).

Four marriages seem best described as "Man Dominated Competitive Axes." The husband strives to assert his male dominance to a pathologic degree, rather clearly in re-

action to his feminine dependent strivings. He needs an admiring wife who supports insatiable narcissistic needs and complies with his rigid expectations, and is angered when she reacts with defiance and disregard. Indeed, her inadequacies as a wife or mother may well produce exasperated frustration. He distrusts her increasingly and undercuts her prestige with the children. The wives are disappointed and disillusioned in the father figure they married who cannot grasp their needs, and, if they are overwhelmed by force, they manage to gain their ends through circumvention. The husbands are rigid paranoids or obsessives, and the wives are poorly organized obsessives or schizophrenics. The marriages are marked by chronic severe mistrust without (except in the least serious instance) any semblance of affection. The family is split into 2 factions by the conflict and mutual undercutting. Although both members are fighting, it is the husband's moral brutality, his disregard and contempt for the wife whom he tries to force into compliance that dominates the picture.

Mr. Reading, a forceful and successful but paranoically suspicious man, sought to control his wife's behavior from the start of the marriage. He was infuriated and disillusioned when she joined a church group against his orders to remain aloof from any organizations. He was dependent upon his mother, who lived in the home for many years; following her advice in household matters in opposition to his wife's, whom he considered incompetent to furnish the house. Marked strife began with the birth of the elder of 2 daughters, for he was clearly jealous of the attention the wife paid the child. He disapproved of everything she did in raising the child, often with good reason, but he competed rather than supported. Mrs. Reading was obviously overprotective of the children, whereas her husband wished to injure them to the hard knocks of life. Violent scenes, filled with Mr. Reading's dire threats and marred by occasional violence, were commonplace. The marriage further disintegrated into a hostile battleground after Mrs. Reading discovered that her husband was having an affair, which she reported to her mother-in-law to gain an ally her husband feared. Mr. Reading never forgave his wife for this betrayal and, apparently to spite her, sold their home in the best section of the city to move into a 2-family house in an undesirable neighborhood. Thus, he struck a foul blow at Mrs. Reading's major preoccupations, her social aspirations and her insistence that her daughters associate with only "proper" companions. The family, previously split into 2 groups, now united against Mr. Reading and refused to eat

meals with him. The difficulties engendered by the wife's indecisive obsessiveness and the husband's paranoid trends cannot be depicted here. Both partners used interviews primarily to incriminate the other and persuade the interviewer to judge in their favor against the spouse.

The second group of 2 families may be categorized as "Woman Dominated Competitive Axes," according to the "Classification of Disorganized Families(2)." The outstanding common feature is the wife's exclusion of the passive and masochistic husband from leadership and decision making. She derogates him in word and deed and is emotionally cold and distant to him. Her attention is focused on her narcissistic needs for completion and admiration. These wives are extremely castrating and their husbands are vulnerable. The husband withdraws from the relationship in an effort to preserve some integrity when defeated in the struggle, and may find solace in alcohol. The husband's function in the family is restricted to providing a living or, if willing, to supporting the wife in her domination of the family. The wife does not fill an expressive, supportive role to her husband and her expressive functions with the children are seriously distorted.

Both Mr. and Mrs. Farrell were closely tied to their parental families. Mrs. Farrell, the youngest of 3 sisters, was very dependent upon her eldest sister, a masculine aggressive woman with open contempt for men, who tended to dominate the Farrell household. Mrs. Farrell refused to live at any distance from her family and spent 2 months each year with them away from her husband. She was an extremely cold, narcissistic woman and a "tease," who flirted constantly but denied her husband sexual relations. Mr. Farrell was a passive man who sought to assert a pseudo-dominance of his family when his men friends were absent. He formed fawning attachments to men, which increased his wife's contempt for him. He was excluded increasingly from the family circle, his opinions disregarded, and felt like an outsider who was barely tolerated. He was closely attached to his mother, whom he helped to support. Mr. Farrell finally took steps to separate unless his wife would detach herself from her sisters. She capitulated but became pregnant in the process of reconciliation. She was ashamed and concealed the pregnancy, and then took it out on her husband. Separated from her sister, she began to drink heavily and carried on open flirtations, or perhaps affairs, neglecting her baby. The husband was pleased. After Mrs. Farrell was seriously disfigured in an accident for which her husband was responsible, she be-

came depressed and withdrew into seclusion until plastic surgery restored her appearance. Mr. Farrell then tried to make amends through becoming a weak and spineless husband who mothered the youngest neglected child. However, he soon developed cancer and his wife displayed a physical abhorrence for him, fearing that she might catch the disease. She refused to nurse him during his terminal illness.

The remaining 2 marriages may be classified as "Dual Immature Dependency Axes." Mutual withdrawal of the spouses and dependency on members of the parental families was outstanding. It is difficult to say which spouse dominated the marriage, though both tried and at the same time resented not having a strong figure who would provide leadership. Resentment of the mates' attachments to their families was prominent. The inability to gain mutual gratification of needs and support led to mounting disregard of the other and increasing emptiness of both lives. These marriages were replete with threats of separation by both members, but each tended to go his or her own way, undermining the other to the children by deeds and attitudes more than by words. Despite the long duration of both marriages, they remained tentative, as if both partners were awaiting and contemplating release.

The Nussbaum's dissension had started shortly after their marriage 25 year ago. Mr. Nussbaum had been largely supported by his elder brother, whom he regarded as a father. Mrs. Nussbaum's father had been fatally injured following business reverses, which her family blamed upon his affiliation with Mr. Nussbaum's brother. Mrs. Nussbaum appeared to side with her family in their accusation of her husband's brother. Mr. Nussbaum considered her attitude to show utter disloyalty as it furnished the finishing blow to his feelings of being excluded by her close-knit family. There was little or no discussion of the matter, but they drew apart. Mrs. Nussbaum was very sensitive lest her husband dominate her, and stood her ground with the help of a violent temper. She refused to accompany him on social engagements essential to his career and antagonized his friends. Mr. Nussbaum felt unloved and unwanted and constantly deprecated. He stayed away from home much of the time, and fostered the impression that he was having affairs, either to spite his wife or to mask his impotence, or both. Weeks would pass when the couple would not speak to one another. The wife found solace in her relationship to her son, and the husband in his seductive attachment to his daughter, our patient.

Although the Newbergs had been in violent disagreement and there had been repeated threats of separation, some elements of good will toward each

other could be uncovered. Mr. Newberg is a very disturbed man, pushing numerous impractical schemes that are often grandiose; talking incessantly in a loud voice; seeking to dominate but with faulty judgment and, although a steady and hardworking provider, he had frightened his wife for years lest he leave his job and launch upon one of his impracticable schemes. He spent little time with his family, partly because of his attachment to his mother and partly because of his wife's attachment to her sisters, which forced the family to live in a home 2 hours from his job. Mr. Newberg resented his wife's attachment to her 3 sisters and mother, and her domination by one sister who constantly disparaged him to his wife and children. Mrs. Newberg claimed that she remained dependent upon her sisters because her husband provided her neither emotional support nor help in raising the children. She considered him impossible to live with because of his demands, his thoughtlessness, and the constant confusion he produced in the home. She remained with him only because she felt the children needed a father but found she had to treat him as a child, humoring him to avoid strife. They blame each other's families for interfering and discourage and disparage each other's interests. The situation reached a crisis when Mr. Newberg wished to move to the west coast because his mother and brother were moving there. He threatened to leave his wife if she would not move and she threatened to leave him if he tried to force the move. Both had intense needs which the other could not begin to satisfy. Although Mr. Newberg had strong paranoid trends and Mrs. Newberg had difficulties in being close, and the hostility was marked, this family offered the best chance of any for some reconciliatory movement, because both showed potential ability to recognize the other's needs as well as their own difficulties.

The portrayals of these marriages are little more than symbolic fragments of the wealth of material collected. Still, they indicate the virtual absence of complementarity in each marriage. Husband and wife do not support each other's needs and the marital interaction increases the emotional problems of both, deprives the spouses of any sense of fulfillment in life, and deteriorates into a hostile encounter in which both are losers. Instead of any reciprocal give and take, there is demand and defiance leading to schism between partners that divides the entire family, leaving the children torn between conflicting attachments and loyalties.

MARITAL SKEW

In 6 of the 14 marriages, this type of schism did not exist, although the family

life was distorted by a skew in the marital relationship. In all, the rather serious psychopathology of one marital partner dominated the home. In some, the dissatisfaction and unhappiness of one spouse is apparent to the other and to the children, but husband and wife manage to complement or support each other sufficiently to permit a degree of harmony. In the others, the distorted ideation of one partner was accepted or shared by the other, creating an atmosphere of *folie à deux*, or even of *folie à famille* when the entire family shared the aberrant conceptualizations.

In all of these families, one partner who was extremely dependent or masochistic had married a spouse who had appeared to be a strong and protecting parental figure. The dependent partner would go along with or even support the weaknesses or psychopathologic distortions of the parental partner because dependency or masochistic needs were met. In contrast to the marriages with overt schism, one partner could gratify rather than combat a spouse's narcissistic needs. It may be significant that no member of these 6 marriages had intense emotional bonds to the parental family, and it is possible that the absence of such alternative sources of gratification tended to hold these spouses together. A striking feature in all cases was the psychopathology of the partner who appeared to be dominant, creating an abnormal environment which, being accepted by the "healthier" spouse, may have seemed to be a normal environment to the children. Considerable "masking" of potential sources of conflict occurred, creating an unreal atmosphere in which what was said and admitted differed from what was actually felt and done. Two and perhaps 3 of the marriages may be classified as "Woman Oriented Self-depreciatory Axes," according to the Classification of Disorganized Families(2), in which the wife's masochistic self-sacrifice to support a narcissistic and disappointing husband was striking. One, and perhaps 2 of the marriages could be designated as "Man Oriented, Self-depreciatory Axes" in which a husband with a meek and self-effacing disposition supported a wife who was an ambulatory schizophrenic.

We shall cite examples in cursory fashion, primarily to illustrate that even though these marriages provided some gratification to the marital partners, the family milieu was as distorted and disturbed as in the case of the schismatic marriages.

The Schwartz family was completely dominated by a paranoid mother who supported the family. Her husband had left her on one occasion, unable to tolerate her demands, but had returned long before the patient, the youngest son, had been born. Soon thereafter the father suffered a nervous breakdown, after which he lived as a sort of handyman around the house and worked as a menial helper in the wife's business. The wife was extremely ambitious for her 4 sons, pushing them and dominating their lives, as well as making it clear that they must not become like their father. She was paranoically fearful of outsiders, believing that their telephone was tapped and that the family was physically endangered because they were Jewish. A severe schism actually existed despite the peace between the marital couple. The mother was intensely protective of her oldest son, a gambler and embezzler, who consumed all of her attention as well as much of the family income. A chronic ambivalent conflict existed between them that tended to exclude the husband and the other sons. The husband did not intervene, but merely told his sons that the trouble in the family existed because they did not obey their mother as he did.

Here the father had abdicated and the mother was a paranoid instrumental leader, while the father supplied no masculine image with whom the younger sons could identify.

Illustrative of the *folie à deux* and the *folie à famille* group, the Dollfuss family lived as European landed gentry in a New England suburb, isolated from their neighbors. The family life was centered in the needs and opinions of Mr. Dollfuss, a successful but paranoically grandiose inventor. The children were raised by a seductive nursemaid of whom the cold and distant mother was intensely jealous. However, Mrs. Dollfuss devoted her life to her husband, catering to his whims, and keeping the children out of his way. Mr. Dollfuss' major interest was an oriental religious sect. He believed that he and a friend were among the few select souls who would achieve a particular type of salvation. Both Mrs. Dollfuss and the nursemaid virtually deified him. They and the children shared his beliefs as well as his grandiose notions of himself, living in what we termed a *folie à famille*. Here, the children were largely excluded from the lives of the parents, the model of the father was an unrealistic one for the son, and the intellectual and emotional environment was estranged from that of the larger culture into which they had to emerge.

In all of these 6 families, the fathers were particularly ineffectual, assuming little re-

sponsibility for family leadership other than earning a livelihood. They were either weak, ineffectual men who went along with wives who were schizophrenic or at least questionably so, or they were disturbed men who could maintain an outward form of capability and strength because of the support of a masochistic wife. In all instances, the psychopathology that pervaded the home was masked or treated as normal.

The analysis of the pathologic environment in these last 6 cases, and of the effects upon the children, cannot be gone into here, but I trust we have shown that we have not simply discarded less disturbed family environments in choosing to focus this paper upon the 8 marriages in which overt schism between the partners existed. In considering the 8 schismatic marriages we do not seek, as emphasized previously, to relate directly the appearance of schizophrenia in an offspring to the marital disorganization. There are many other factors in the family environment which we are studying that affect the children, but they all bear some relationship to the personalities of the parents and the atmosphere created by their interaction. We are only seeking to describe bit by bit what this family environment is like, until we can assemble the fragments into a meaningful description of the whole. We are still occupied with the grossest factors, for unless we start with what appears fairly obvious, these factors may be overlooked during our preoccupation with subtleties. In this presentation, we have paid minimal attention to the individual personalities of the parents in order to concentrate upon problems created by their interaction.

DISCUSSION

We find a number of features in these marriages that are theoretically adverse to the "normal" developmental process of a child. In these families each parent constantly denigrates and undercuts the other, making it clear to the children that each does not respect or value, but rather dislikes or hates the other. Each parent more or less openly expresses fears that a child will resemble the other, and a child's resemblance to one parent is a source of concern or rejection by the other parent. One

or both parents seek to win the child away from the other. The boundary between the generations is violated. A child may feel the burden of being expected or required to complete the life of one or both parents; and this creates a block to growth into an independent individual. A child may be used and needed as a replacement for the spouse. There is excellent opportunity for intensification of the Oedipal rivalry rather than for its resolution. The child can insert himself in the wedge between the parents, becoming inordinately adept at widening the breach and becoming caught in the incestuous concern that the parent can be seduced or might seduce, as well as in the guilt over hostile-destructive impulses toward the other parent. A parent of the same sex with whom the child should identify during latency and adolescence who is not an acceptable love object to the other parent but is hated and despised, cannot provide a model through which a child can achieve mature identity. Potential homosexual trends, which play a large role in schizophrenia, are opened. Many other serious impediments are placed in the way of the child's achievements of a stable identification with a parental figure, a requisite to the formation of a stable ego-identity by the end of adolescence. In addition, children of a rejected marriage are likely to feel rejected themselves. Caught in the anxiety that a needed parental love-object can be lost through separation of the parents, the children may devote much energy toward balancing the precarious marriage. The stronger the incestuous tendencies, the greater the need for protection by the presence of both parents. When one or both parents have paralogic and scattered ways of thinking and behaving, the difficulties are further heightened.

SUMMARY

The careful scrutiny of the 14 families containing schizophrenic offspring reveals

that the marital relationships of all parents were seriously disturbed. Eight of the families were split into 2 factions by the overt schism between the parents. In these schismatic families the parents repeatedly threatened to separate; one spouse sought to coerce the other to conform to rigid expectations and aroused defiance; difficulties of almost any type engendered recriminations between parents rather than mutual support. The parents derogated and undercut one another, and thus the child could not use one parent as a model for identification or as a love object without antagonizing the other parent. The other 6 couples lived together in reasonable harmony, but the family environments provided by their marriages were badly distorted or "skewed" because in each marriage the serious psychopathology of the dominant parent was accepted or shared by the other. Studies now in progress will seek to clarify further the difficulties in these marriages, the personalities involved, and the effects upon the children.

THE PHYSICIAN AND TESTAMENTARY CAPACITY¹

GENE L. USDIN, M.D.²

The accumulation of property often is a reward for intelligence, industry and opportunity. Its acquisition is not only a source of pleasure, but a potent factor in the evolution of a progressive civilization and culture. The need of an individual to identify with and attempt to secure happiness for his progeny, other relatives and valued friends as well as to contribute to causes, foundations and institutions is one of the signs of a healthy personality. Provided the testator complies with the limitations imposed by law, the courts jealously guard this right to dispose of property as the owner sees fit. Testamentary capacity, the legal rules concerning the competency of a person to make a valid will, is one of the prerequisites. The physician, in the role of expert witness, is frequently called to evaluate testamentary capacity. Participation of the physician in court actually is a fairly simple matter requiring only the presentation of medical knowledge in a non-partisan and non-technical manner. Some branches of legal medicine (principally psychiatry) require special understanding of legal standards. Medical experts too often neglect the relatively brief preparation required to ascertain criteria that the court expects the medical expert to apply in the particular situation.

A leading Louisiana case(1) seemed to connote the basic humanistic issue involved when it gave the following rule in 1880:

The real question is, whether the brain or other physical organ . . . through which the action of the mind is manifested, is so diseased or impaired as to make it an untrustworthy vehicle for the conveyance of the true wish or will of the testator, unbiased by any delusion which may be the result of such disease.

The purpose of this paper is to review the psychiatric aspects of legal propositions involved in evaluating testamentary capacity.

Ideally this evaluation falls into the province of the psychiatrist, but often the determination of testamentary capacity arises after the testator has died and therefore is one of hind-sight; physicians attending the patient during the period of the writing of the will, whether they be general practitioners, surgeons, internists, etc., become the main medical experts. Also some smaller communities do not have psychiatrists.

Our laws, in attempting to protect the sanctity of testamentary capacity, have placed it in a type of Valhalla; they recognize the right of an individual to dispose of his property as he personally wills as a paramount privilege that our society should guarantee. To invalidate a will is more difficult than to void a contract or to have an individual declared insane or criminally irresponsible. The voiding of a will can be accomplished on but 3 grounds: lack of testamentary power, lack of testamentary capacity or the presence of undue influence. Concisely stated, undue influence invalidating a will is that which substitutes the wishes of another for those of the testator(2). This factor has been utilized frequently, has prescribed fairly precise conditions, and when appropriate seems to have considerable merit for use in contesting a will. In at least one state, Louisiana, undue influence is not recognized as grounds for invalidating a will(3) although that state recognizes the principle of the doctrine, at least in part, by the limitation of bequests to physicians and ministers attending the patient during the terminal illness(4). Testamentary power, which is defined as the privilege or right of a person to dispose of his property by will(5), is created by statutes, is within legislative control and lies solely within the province of the law. These statutes vary from state to state and nation to nation; they prescribe specific conditions under which a will may be considered a legal document, and no court has the power to dispense with any of the prescribed requisites of its particular jurisdiction.

Various attempts have been made to estab-

¹ Presented at the Southern Psychiatric Association Meeting, Washington, D. C., October 2, 1956, and the Eleventh Annual Meeting of the Law Institute, Jackson, Miss., December 7, 1956.

lish arbitrary standards of testamentary capacity. Before the evolution of present day concepts, 3 fairly well delineated states in the history of the law governing testamentary law are discernible. The initial period would seem to date from earliest court decisions on record down to 1848. During this period each contested will involving testamentary capacity was determined on its own merit and based on the thought of the specific court in which the case was tried. Accordingly wide latitudes prevailed. In 1848 Lord Brougham of England promulgated his decree (6) which had far reaching consequences. It stated that mental disease was so subtle and intangible that no legal tribunal could safely undertake to define its degree, and the only wise course was to hold any degree of insanity as unfitting to testamentary capacity. During this same period, American law adopted a different concept which made the mere possession of understanding sufficient to establish testamentary capacity. Such a low standard for establishing testamentary capacity resulted in one court stating that "weak minds differ from strong minds only in degree; unless they betray a total loss of understanding or idiocy or delusion, they cannot possibly be considered unsound (7)."

In 1870, Lord Chief Justice Cockburn of England made his epoch making decision (8) which still stands as the basis for the modern legal concept of testamentary capacity. His basic proposition concerns the saneness or insaneness of the testator for the purpose of making a will at the specific time the will is written. The essence of his rule states that the person making the will knows that he is making a will, knows the nature and extent of his property and knows the natural recipients of his bounty. Any attorney or psychiatrist who deals with last wills and testaments would do well to review the full text of Lord Cockburn's opinion. This excellent but somewhat loose principle has undergone modifications and elaborations by nearly all 48 states and the District of Columbia. Different interpretations actually have been provided at various times in the same state.

With these somewhat broad and ambiguous criteria, the medical expert has to render an opinion regarding testamentary capacity.

While this may appear somewhat appalling, it should be borne in mind that if the medical expert understands the psychiatric status of the patient, especially at the time the will was made, and if he bears in mind the 3 generally accepted criteria of testamentary capacity, he will not only be of aid to the court but also will make a most satisfactory court appearance. He should be prepared to accept the fact that all too often the courts neglect reputable medical testimony when it is contradictory to non-medical testimony. Case after case can be found where the court has paid absolutely no attention to the opinions of the experts because the behavior of the testator as detailed by lay witnesses pointed in the opposite direction (9). Courts have frequently castigated medical opinions regarding testamentary capacity (10, 11, 12).

The writer recently appeared in a case (13) in which 4 medical experts including 2 physicians who attended the patient during the period when the will was written, testified that in their opinion the testatrix was unable to fulfill the accepted criteria of testamentary capacity. Both sides had numerous lay witnesses, but the side seeking to uphold the will produced no medical experts. The trial judge upheld the will. It was not until after a petition for rehearing had been granted that a compromise was achieved whereby the side seeking to invalidate the will was granted 30% of the estate in contest.

The psychiatrist encounters theoretical concepts which are difficult for him to accept, e.g., some courts have held that a person may be competent to dispose of a small estate among a few individuals by simple gifts, and yet be incompetent to dispose of a large estate among a great number of persons by complex and involved conditions (14, 15, 16). The psychiatrist, in applying knowledge of human behavior and intellect, finds this viewpoint completely tenable. However, other courts have contradicted this view, stating that testamentary capacity is one of capacity to make a will, not to make the particular one offered for probate (17). In trying to understand the rationale of this latter opinion, the psychiatrist can only become perplexed and attribute some legal opinions to the fact that law is a retrospective discipline based upon previous decisions. There are

definite values in the law being a discipline which changes cautiously and slowly. Its conception of human behavior has not yet caught up with prevailing psychiatric thought.

The function of the medical expert is to apply his training and experience in considering functional and somatic illness in the light of criteria for testamentary capacity. It should be kept in mind that there are numerous physical conditions that may cause either transient or permanent mental incompetency. There are several psychiatric illnesses that permit a psychotic person to have more lucid intervals during which his intellectual capacity is significantly increased. A person may be psychotic or may be in an institution for many years, but still may be able to fulfill the requirements for testamentary capacity. The important factor to be considered by the medical expert is whether or not any essential element of testamentary capacity is impaired by the illness. The majority of cases in which testamentary capacity has been questioned occur in a fairly small group of conditions. These conditions frequently intermingle.

The diseases of old age constitute the largest group of conditions upon which testamentary capacity can be attacked. With an ever increasing number of people exceeding the Biblically allotted span, this group will constitute a continuously larger percentage. Extreme old age does not of itself disqualify a person from making a valid will. Old age becomes an important evidentiary fact only when found in connection with mental incompetency. Numerous cases can be found upholding agreements and wills made by individuals in advanced years. One such case noted is that of a 94-year-old testator whose last will was upheld (18). Another will which was upheld was made by a 96-year-old testator who died 4 years later (19). Still another concerns a testator who made a valid will at the age of 101 (20).

Most physicians appreciate that senility is not a chronological fact. It varies with the individual's physiological status, with the personality, with environmental factors and with superimposed emotional illness. Sigmund Freud was active and productive until a few weeks before he died at the age of 83.

It was during the last year of his life that he published what many consider one of his most monumental works, "Moses and Monotheism." Justice Oliver Wendell Holmes was active in the United States Supreme Court at the age of 91. Titian painted one of his greatest masterpieces at the age of 98. Michel-Eugene Chevreul, who died in 1889 at the age of 103, presided at meetings of the Academy of Science in Paris at the age of 85 and was active in scientific circles at the age of 100 (21).

The difference between senility and senile dementia is frequently only a shade, yet the psychiatrist often has the responsibility to differentiate the conditions. Some states (e.g., Louisiana) consider that "Where the medical testimony shows that the testatrix was suffering from senile dementia she is considered *mente captus* and is presumed incapable of a lucid interval (22, 23)." The psychiatrist, in having to determine the point at which simple senility ends and senile psychosis begins, has to make a decision that not only might be considered an anthropological and philosophical one, but one in which opinions of physicians vary markedly. In one recent case involving testamentary capacity in which the author participated, the testatrix was a 78-year-old widow who had made holographic wills 5 and 6 years prior to her death in October of 1953 (24). She spent the last 13 months of her life in a mental hospital, during which time she was a deteriorated and demented individual. The family physician who had treated her for the last 15 years of her life had noticed marked mental and physical changes which began in 1942. The legal question concerned the testatrix's capacity for making the wills of 1947 and 1948. There was a substantial history of disorientation, eccentric behavior, depressive episodes, possible paranoid ideation, frequent expressions of being mortally afraid of the major beneficiary of her will and marked recent memory defects. One factor of the decision in the case rested upon the determination of whether her symptoms were those of a senile individual or of a senile psychotic at the time the wills were written. Arrayed on the side seeking to invalidate the will were the family physician, two psychiatrists who had been in charge of the pa-

tent's terminal hospital course and a third psychiatrist who was being utilized as an additional expert. The side seeking to uphold the will placed on the stand a psychiatrist who had seen the patient briefly during the terminal hospitalization and an internist who had never seen the patient; for further consultation they had the services of another psychiatrist who helped in the framing of the medical portion of their case. It is easily understandable how two such factions can exist, but it is unfortunate that such courtroom disagreements tend to undermine the court's and public's opinions not only of the competence, but also of the integrity of physicians.

The lengths to which courts go to protect a simple senile person's right to make a will is best emphasized by citing one court's recent statement that "... Neither old age, nor its infirmities, including untidy habits, partial loss of memory, inability to recognize acquaintances and incoherent speech will deprive a person of the right to dispose of his own property (25)."

A fine point for the psychiatrist can be the differentiation of senile dementia from cerebral arteriosclerosis if such differentiation is possible. Courts have recognized that cerebral arteriosclerosis is not identical with senile dementia (25). It is important to keep in mind that senile dementia is a progressive disease without better or "more lucid" intervals, whereas the arteriosclerotic may have better and worse days or periods. Accordingly one would anticipate that some cerebral arteriosclerotics may on certain days be able to fulfill the criteria of testamentary capacity, whereas on other days they may be unable to do so.

Alcoholism and drug addiction are other illnesses which often give rise to a contest of capacity. Here again the important issue is the ability of the individual to satisfy the criteria of testamentary capacity on the day the will was made. A person may be a chronic alcoholic but still possess testamentary capacity on less intoxicated or non-intoxicated days. Still other individuals may have no known or significant alcoholic problem, but on the day the will is drawn they may have been so intoxicated that the will cannot be considered valid. Simply stated,

alcoholism or drug addiction to vitiate the testamentary act must be such that the testator at the time of the execution of the will was so overwhelmed by the toxic substance that he was rendered incapable of fulfilling the criteria of testamentary capacity; or alcoholic or drug consumption must have been indulged in for such duration as to produce permanent degeneration of the brain.

The toxic psychoses associated with altered body physiology during various somatic illnesses can invalidate a will if the realm of testamentary capacity is affected at the time the will was made. Thus a dying patient may be so confused, disoriented and agitated that he would be unable to make a valid will. All too often it is suddenly realized, with the patient on his death bed, that no will has been made, and frantic scurrying produces a document for the dying individual to sign. Under this stress, in addition to possibly being psychotic, the testator is not helped by the thought that this is his last will and testament. Undue influence is more likely in a person so weakened and defenseless. Many of the febrile deliria, altered states of blood chemistry (*e.g.*, uremia) or stupors associated with severe illnesses can alter mental equilibrium. In one recent case a group seeking to validate a will maintained that the testatrix was mentally incompetent, due to uremic delirium at the time she was seen by two psychiatrists and subsequently might have had a reduction in nitrogenous wastes to such an extent that the delirium was not present when she shortly thereafter made a will (26). It is especially in this group of conditions that the concept of lucid interval might be applicable and in which the acumen of the psychiatrist may be strongly tested. **The law recognizes that a will executed in a lucid interval by one who was before and afterward a "confirmed" lunatic is valid (27, 28, 29).** It is when the question of lucid interval is pertinent that it is especially advisable for the physician to be present at the specific time the will is being drawn up. Attorneys too often fail to utilize the opportunity of having a psychiatrist present at the time the will is made if they anticipate a contest possibly developing on the grounds of testamentary capacity. **Some attorneys may see this latter technique used as a possi-**

ble presupposition by the side contesting the will. The psychiatrist can also serve as an advisor to the attorney by pointing out when "more lucid" intervals can be expected for the particular testator, *e.g.*, the phenomenon of mental fatigue in senile individuals would make it appear advisable to execute the will early in the day. If the psychiatrist believes that the testator might have a "more lucid" interval at a later date, he might suggest a postponement of the drawing up of the will. It is important to remember that delaying the execution of the will can result in two major complications. The intended testator might die or might become less mentally competent.

Courts have recognized that many diseases or injuries if severe enough can cause permanent, or at least temporary, mental incompetence. Thus brain injuries, neoplasms of the brain and cerebral vascular disorders can render a testator incompetent to execute a valid will. It is a matter of history that Mrs. Fillmore, widow of President Fillmore, manifested symptoms of impaired mentality before she had an apoplectic stroke. She made 2 wills within 8 months of the stroke, but on a physician's testimony she was judged to be insane and incompetent (30).

Dementia paralytica in itself, does not void testamentary capacity (31), unless some essential of testamentary capacity is impaired. The same rule would seem applicable to chronic encephalitis, congenital brain anomalies and epilepsy.

Around the turn of the twentieth century considerable thought was given to the problem of aphasics making a will (30, 32, 33, 34). Bateman cites a case of an English aphasic who acted as mayor and municipal counselor, signed his mail with his left hand and also wrote his will which was recognized as valid by the courts (33). Bramwell (34) cited an especially interesting case of a patient suffering from motor aphasia and a right hemiplegia who indicated by pantomimic answers that she was able to make a will. The patient was asked to express "Yes" by nodding her head and squeezing the lawyer's hand and to express "No" by shaking her head. First she was asked whether she wanted to make a will, and then a list of possible recipients of her bounty was read

to her. She was then asked to answer "Yes" or "No" if she wished to bequeath anything to each of them. After the 4 close relatives were designated and the broad class of "anyone else" was established, she was asked to whom she wanted to leave her money. To her sister she indicated "Yes" and to the others she indicated "No." This was repeated several times. When she was asked whether she wanted to leave all her money to her sister, she again indicated "Yes" several times. The witnesses and medical experts also had the advantage of her facial expressions and manner and felt these were compatible with her answers. The aforementioned cases emphasize the necessity for initiative on the part of medical experts and attorneys in dealing with aphasics. Some aphasia sufferers sustain considerable intellectual deficits, others relatively little. The form of aphasia is of the greatest importance in establishing testamentary capacity, and each case must be decided on its specific pathology. For example, there are patients with aphasia who cannot comprehend the spoken word but can comprehend the written word. Doctors and attorneys having no intimate knowledge of aphasia can come too quickly to the conclusion that the patient is not in a fit mental condition to make a will. This is not particularly surprising, because it was not too long ago that aphasics were considered insane. With some ingenuity physicians and attorneys can help give the patient the opportunity to dispose of his property as he properly wills.

Eccentricity, bad manners and grotesque conduct in themselves are not evidence of insanity, especially where they are habitual in the testator (35). The eccentric person may make a valid will, notwithstanding the peculiarity of his conduct (36, 37).

The fact that a person believes in witchcraft, clairvoyance, spiritual influences, premonitions, mind-reading, transmigration of the soul or occult religions does not affect the validity of his will. A man's belief cannot be made the test of his sanity. Marked penitence (38), violent temper (39, 40), moral depravity (41, 42), religious fanaticism (38, 43) or eccentricity regarding health, wearing apparel, hobbies, table manners and language (44, 45) in themselves do not

render the testator incapable of making a valid will. The person may be obstinate, subject to strong passions and prejudices and unreasonable in his hostilities but yet not devoid of testamentary capacity. Belief in spiritualism does not necessarily affect the testator's knowledge of his relatives and his property (43, 45, 46). In instances where the testator labors under the delusion that the spirits of the dead or some other ethereal source is directing him in his business, specifically the will, a will may be considered invalid (47).

Delusions of marital infidelity are fairly frequent in severe mental illness. They are especially prone to occur in the involuntal psychoses and in senile psychoses. If the delusion can be shown to affect the natural recipients of the testator's bounty, the will must be considered invalid. Courts attempt to emphasize the distinction between the belief in a wife's unfaithfulness under external circumstances and a belief based on psychotic delusion. Thus one court has stated "... to justify the rejection of the will, it must be established that the false belief is a symptom of a deranged mind and not the result of an impression produced by extraneous circumstances. The burden is on the petitioner to prove the nonexistence of the extrinsic evidence on which the belief rested" (48). The irony of this is that a person may disinherit an individual on false information (e.g., false information regarding a wife's unfaithfulness) or undue inference from some observations, and the court will uphold the will. If the individual has a delusion regarding an anticipated recipient of his bounty and the delusion affects the will, then the will can be invalidated.

Delusions of grandeur or poverty are other types of aberrant behavior which may invalidate a will. Here the individual's inability to appreciate the nature and extent of his property is usually the invalidating factor. Insane delusions have produced many interesting cases. There is a case in Indiana in which the testator believed he could locate hidden treasure by means of a small metallic ball suspended from a thread (49). The testator spent considerable time going over fields trying to locate treasure and dug so many holes that he became a nuisance

and had to be stopped. Evidence of this behavior did not invalidate the will. To summarize, courts consider delusions as sufficient to destroy testamentary capacity when they cause a disposition differing from that which it might reasonably be found that the testator would otherwise have made.

Illiteracy in itself has no probative value for it does not necessarily indicate incapacity for understanding. It can many times, however, be indicative of mental deficiency. Mental deficiency can invalidate a will, but the deficiency would have to be of such extent as to vitiate one of the criteria of testamentary capacity. Average intellect is unnecessary; thus one might anticipate that some high grade morons could make a valid will whereas all idiots and imbeciles would be unable to do so. In one recent case, the court decided that an adult with the intelligence of a 5-year-old lacked testamentary capacity (50). Therefore intelligence testing of the possible mental defective can become an important procedure for the psychiatric evaluation of testamentary capacity. In serving the court the psychiatrist should be aware that legal definitions often differ from those of medicine, e.g., some court decisions have differentiated idiot and imbecile not on the basis of intelligence levels but on the basis of an idiot's "lacking mind from birth" and the imbecile's being "mentally deficient as a result of disease" (51)."

SUMMARY

The evaluation of testamentary capacity represents a field requiring serious psychiatric consideration. While considerable publicity and work have recently been afforded the problem of criminal responsibility, little can be found in recent psychiatric literature regarding testamentary capacity. There have been some noteworthy exceptions, and Davidson's clear, simple and concise chapter in his recent book (52) is a major contribution.

No court or tribunal can set up a standard by which mental capacity may be unerringly tested. No jurist or psychiatrist has indicated a precise point where sanity ceases and insanity begins. Perhaps it would be easier to decide the exact instant when dusk surrenders to darkness.

The psychiatrist faces the problem of proper expert testimony based on the application of psychopathology to criteria set by the law. These criteria may appear quite ambiguous or they may be satisfied in a manner which the psychiatrist may feel injustice is being done. The psychiatrist may be distressed by some of the discourtesies and the weight afforded his testimony.

The conditions under which testamentary capacity can be contested are fairly limited. The value of having the psychiatrist present at the time the will is being drawn up is important, especially when the premise of a lucid interval is to be utilized. In the majority of cases where wills are contested, the psychiatrist rarely has the opportunity to examine the testator and has to depend on the available history. He must obtain facts as best he can and render an honest opinion as to testamentary capacity. The lawyer's duty to his client is to give him the benefit of the best legal ability of which he is capable; so naturally a lawyer, consulting a psychiatrist, will try to present witnesses who primarily favor his side. Progress has been made in many states by the appointing of impartial medical experts for jury commissions and cases involving personal injury liability. It would be an important step to have such impartial opinion applied in cases involving testamentary capacity.

There is increasing awareness on the part of the legal profession of the real contributions which an understanding of behavioral mechanisms can make toward better conceptualization of the law and its procedures. Psychiatry is the medical specialty which has the closest contact with law. It too is directly concerned with the appropriate regulation of human behavior in a healthy manner. Psychiatry, however, is neither as pragmatic, authoritarian or precise as the law. Although present-day dynamic psychiatry recognizes the vital impact of the unconscious motivation of behavior, law leaves no place for such recognition although it is beginning to take hesitant steps in that direction.

USE OF MILTOWN (MEPROBAMATE) WITH PSYCHOTIC PATIENTS

VERONICA M. PENNINGTON, M.D.¹

The present study of the tranquilizing drug Miltown² (meprobamate) was undertaken as part of a larger investigation of the value of 6 ataractic drugs in hospitalized psychotic patients (1, 2). Altogether, 1,250 patients received one or more ataraxics for periods of up to 18 months. Of this total, 300 were treated with Miltown.

SCOPE AND METHOD

Patients were chosen at random; some had improved or had been brought to remission on other ataraxics and had had a psychotic relapse on placebo; some did not do well on the tranquilizing drug they were taking and were changed to Miltown. Most of these patients had had electric or insulin shock therapy. Four had been lobotomized. The past histories of these patients and their response to other therapies were well known to us so that the comparative results could readily be determined. Many of the best prospects for betterment had already been returned to their homes because of the beneficial action of other tranquilizers, leaving those patients whose prognosis was poor to be treated with Miltown. They ranged in age from 15 to 84 years, and had been hospitalized from 1 week to 55 years. Most of this group had been psychotic for over 3 years, many of them for 20 years; the average duration of psychosis was 16 years.

Our beginning dose was two 400 mg. tablets twice a day. This was increased until a favorable response was noted. Most of the patients were seen by me daily and the dosage of Miltown adjusted to their individual needs until a stabilizing dose could be determined. The average required dose was found to be eight 400 mg. tablets during a 24-hour period, although a few patients required as much as 24 tablets.

Blood counts were done on all patients

taking this medication and showed no abnormalities. Blood pressure readings and physical and psychiatric evaluations were made prior to, during, and after treatment. Dosage, weight and sleep charts were kept, as well as charts of physical and emotional changes. Semi-monthly recordings of these changes, as seen by the patient himself, the psychiatric aides, his relatives and myself were also kept.

For control, 100 patients were given placebo for 2 months, followed by Miltown, in addition to 200 placed directly on the active medication. In another trial, involving 196 patients, 6 ataraxics including Miltown were investigated in a double-blind study. The active medications and placebo were coded and rotated in 4-week courses, the druggist being the only person who knew the code. This made each patient his own control as well as a control for all in the group.

One-third of the patients received Rorschach and Bender-Gestalt tests to determine the degree of their normality or psychopathy after treatment as compared with those qualities before treatment.

RESULTS

Results of the study are summarized in Table 1. Of the 300 patients treated with Miltown, 3% showed complete remission, 35% were greatly improved, 46% showed some improvement, and in 16% no significant change was observed.

Best results were achieved in a group of 30 paranoid schizophrenics, all of whom experienced some benefit from the drug, 60% showing great improvement, including 10% who experienced complete remission. Cata-tonic and hebephrenic types and patients suffering from symptoms of organic brain disease were less often helped, important improvement occurring in about one-third of these cases. Other categories were not studied in sufficient numbers to warrant generalized judgment as to results. Physical gains due to better sleep habits and relaxa-

tion were made by about 50% of the patients.

In the double-blind study in which patients received active medication and placebo in 4-week courses, Miltown showed an improvement rate of 60%. When placebo was administered as the first medication, improvement at the end of the month was less than 1%. In later courses, when placebo was given following active medication, improvement rose to 68%. These later courses of placebo must therefore be discounted as reflecting in reality the delayed action or continuing effects of the previously taken drugs. When placebo was given to 100 patients for 2 months, in the present study, prior to the initiation of Miltown treatment, no sustained improvement was observed, the small gains temporarily made being lost over the longer period of sustained placebo administration.

Of the 100 patients who received psychological tests, 8 had normal protocols following Miltown treatment and were judged to be in remission. Nineteen were in partial remission, showing an intellectual control of their symptoms and a capacity for empathetic relationship which made them appear normal; some of these showed psychotic residuals. Fifty-two patients were rated as

improved, including 48 who had not been testable prior to medication; these latter all continued to show a psychotic record. Twenty-one patients remained untestable. Paranoid ideation showed improvement in a number of cases. Several patients who had been actively hallucinated and delusional prior to taking Miltown showed no schizophrenic fantasy in remission. Homosexual trends were not affected.

Thirty-three patients were returned to their homes following Miltown treatment, and 27 were ready to leave, awaiting relatives to take them. Five patients hospitalized over 10 years are doing well at home on Miltown. All received prescriptions for maintenance doses for use after their release. Five of these patients returned to the hospital following recurrence of symptoms, only one having continued to take the medication at home as prescribed.

SIDE EFFECTS

Hypotension on large dosage occurred in 3 cases. The first patient, a schizophrenic catatonic receiving ten 400 mg. tablets twice a day, because of markedly assaultive be-

havior and banging his head against the wall, was considered by the psychiatric aides to be in shock. When seen by me, he was sleeping soundly but could be aroused. His blood pressure was 90/60, pulse 58, regular in rate and rhythm. Respirations were 12 per minute. He was given 2 cups of coffee and was walked about the ward by 2 psychiatric aides. He continued to be up and about the remainder of the day.

The second case, on a beginning dose of ten 400 mg. tablets twice daily, was transferred to the hospital ward by the officers of the day when she could not be aroused. Her color was good, extremities warm, respiration 12 per minute, pulse 50, blood pressure 70/50. When her name was called, she opened her eyes and turned on her side. Soon her blood pressure was 100/60; normally it was 130/70. She was given passive exercise and caffeine sodiobenzoate, which reduced the period of beneficial sleep produced by her medication.

A third patient accumulated sixty-two 400 mg. tablets of Miltown over a period of weeks by hoarding the 8 tablets given to her daily and picking up tablets discarded by other patients. She became somnolent in the afternoon of September 29 and since she often had periods of catatonic inactivity, the aide administered her usual dose of four 400 mg. tablets of Miltown, bringing the total intake of this medication up to sixty-six 400 mg. tablets. At 3:00 P.M., I was called because she could not be aroused. Her color was good, she flinched at the touch of ice to the abdomen, blood pressure was 120/70, pulse was regular in rate and rhythm. Her blood pressure dropped to 100/70, pulse was 88. She was given 2 ampules of coramine and caffeine sodiobenzoate. A lumbar puncture, blood sugar and coagulation time were done since the cause of her comatose condition was not yet certain. The following day her blood pressure went up to 120/70. Pulse rate was 120. She moved slightly to painful stimuli and yawned occasionally. She began to move her arms and legs late on the second day. Still later that day she sat up and on the third day after admission to the hospital, she ate well and admitted taking the excessive dose of Miltown.

One patient on a regimen of ten 400 mg.

tablets of Miltown twice a day had one *grand mal* seizure. Schizophrenics frequently have a convulsion and I have always felt that shock therapy predisposes them to seizures. Since this patient was a schizophrenic and had had innumerable shock treatments, the cause of the convulsion seems to me uncertain.

Allergic reactions to this medication have been reported (3) but none were present in this series. No nasal stuffiness, vomiting, diarrhea, muscle aches, pyalism, or skin rashes occurred.

DISCUSSION

Previous investigations of Miltown have reported on the value of the drug as a tranquilizer in neurotic conditions, particularly in anxiety and tension states (4, 5, 6). The present study shows that Miltown is also effective for gross symptomatology and for marked deviations from normal emotionality, as in the psychoses. Disturbed, self-destructive, assaultive, enuritic patients and those showing the noisy psychomotor hyperactivity of catatonic excitement, manic stimulation, and epileptic furor become tractable, quiet and capable of co-operation. Aggressiveness, irritability, hostility, and belligerence are relieved. Even the most pugnacious and noisy patient can be maintained in a quiet, calm condition on the dosage best suited to that individual. We have been able to discontinue hydrotherapy and all forms of shock treatment with patients receiving Miltown medication.

Improvement is more easily attained in hyperkinetic than in lethargic individuals. The duration of the psychosis is also important in the prognosis, but this appears to be less significant than whether the patient is overactive or withdrawn.

An unexpected result of Miltown treatment not mentioned in the literature is that of staunching the odor of perspiration. Four of our patients have for several years been known to have a strong acrid perspiration odor which no amount of bathing changed. Under Miltown treatment bromhidrosis subsided completely. One can only speculate as to the reason, but a possibility may be that the decreased emotional turbulence brought about by the drug resulted in re-

duced activity of the sudoriferous glands, whose secretions contain odorous substances, and which are principally responsive to emotional stimulation(8).

The action of Miltown is gentle and free of side effects. In contrast to chlorpromazine and reserpine, Miltown does not act upon the autonomic nervous system(9). Unlike all other ataraxics, it has a relaxing effect on skeletal muscles in addition to its tranquilizing effect on the central nervous system(10, 11).

Miltown calms and quiets without clouding consciousness, and enables the patient to secure restful sleep without hangover. Except in overdosage, the patient can be aroused at all times to attend to his personal needs. His environment does not disturb him. Logical thinking returns and in many cases, when environmental tensions lessen, delusions and hallucinations are obviated with the support afforded his ego by this medication.

While striking results were not obtainable in all cases, Miltown in the dosages used, proved at least as effective as the other ataraxics studied, despite the fact that the patients treated were the less promising cases. Because of these comparatively good results, and also because of its exceptional safety and negligible side effects, I consider that Miltown is the drug to be tried first in the treatment of emotional disturbances. In those cases where good response is not achieved, more toxic medications may be risked.

In my opinion, the beneficial results of Miltown are probably symptomatic, not etiological, just as insulin is in diabetes. It is assumed that even upon discharge continued medication will generally be necessary in psychotic patients for continued mental health.

CONCLUSIONS

Miltown (meprobamate) was studied in 300 hospitalized psychotic patients. In the dosage range from two to twenty-four 400 mg. tablets daily, the drug produced complete remission of symptoms in 3% of patients, striking improvement in 35%, some improvement in an additional 46%, and no significant change in the remaining 16%.

Physical gains resulting from better sleeping habits and relaxation were made in about half the patients. Paranoid schizophrenics appeared to derive greatest benefit from the drug.

Noisy, assaultive, eneuritic, delusional, hallucinated patients were generally relieved of these symptoms, although psychological residuals usually remained. Psychological testing showed improvement in the Rorschach and Bender-Gestalt tests with an effort, in many cases still showing psychotic traits, to reach healthy relationships with their environment. Eight patients tested normal after taking the drug. Most of the remainder showed increased ability to sublimate their abnormal psychological drives, and to get along in their milieu.

Thirty-three patients were able to be discharged from the hospital following Miltown treatment, and 27 were ready for release as soon as arrangements for family custody could be made.

Retarded, blocked, hypoactive patients were not as markedly benefited as the hyperactive, noisy type.

The safety of Miltown and its almost complete lack of side effects, except for hypotension in high dosage, makes it an ataraxic of choice. It is an important addition to the armamentarium of the neuro-psychiatrist.

CLINICAL NOTES

THE EFFECT OF A SPECIAL DIET ON HOSPITALIZED SCHIZOPHRENIC PATIENTS¹

SAMUEL BOGOCH, M.D., PH.D.²

Twenty-two young hospitalized schizophrenic patients (17-38 yrs.; 12 female, 10 male), most of whom had demonstrated ability to recover from previous acute psychotic episodes, were given a diet essentially free of aromatic amino acids for 3 weeks.³ In the following 3 week period, one-half of the patients remained on the deficient diet, while the rest received supplements of phenylalanine (5g. per 100g. protein) and tryptophane (1.8g. per 100g. protein). The assignment of patients for the control diet of the second period was made at random by the dietician, in advance of the first dietary period. It was impossible to distinguish the deficient diet from the control diet in terms of appearance or palatability. Clinical evaluation was performed independently by the ward staff and the author. Neither knew which patients received the deficient diet and which received the supplemented diet, nor did the patients know that all of the diets were not identical. Caloric intake was between 2400 and 2700 calories per day. The unavoidable protein ingested on the test diet did not exceed 2.5gm. daily. "Clnsivol" multivitamin capsules were given once daily to insure adequate vitamin intake. No other food was available to the patients.

Of the 22 patients on the deficient diet,

13 (8 males, 5 females) became clinically worse, and 9 showed no significant change.

In the second 3 week period, of the 13 patients whose condition had deteriorated, one had to be removed from the project to be given ECT, 8 remained on the deficient diet, while 4 fell into the control group receiving an adequate intake of aromatic amino acids. Of the 8 who remained on the diet, 5 remained worse, while 3 returned to their pre-diet level (still unimproved). Of the 4 who subsequently received an adequate amino acid intake, all showed improvement. One was better than her pre-diet level for a week, then slipped back, while the other 3 gradually improved to their pre-diet level of adjustment only.

Of the 9 patients (2 males, 7 females) who showed no significant change in the first 3 weeks on the deficient diet, 5 fell into the group remaining on the deficient diet, while 4 received the adequate control diet. Of the 4 who received an adequate intake, one improved to a slightly better than pre-diet level, while 3 showed no significant change. Of the 5 who remained on the diet, no significant change occurred.

It is clear from the results presented that the diet is not to be considered a therapeutic agent. In fact there is evidence that it is psychotoxic. While improvements attributable to placebo effects or to spontaneous recovery would be expected to take place in about one-third of the patients, in the present experiment, none showed any significant improvement. Some of the factors, both dynamic and metabolic, which may be responsible for the psychotoxic effects observed, form the subject of further experiments, and are discussed in a detailed report of this study which will appear elsewhere.

¹ This study was conducted under the auspices of Dr. W. C. Gibson and the department of neurological research, University of British Columbia Medical School, Vancouver. The author is grateful to Drs. A. M. Gurr, A. Davidson and F. McNair for making available the clinical facilities of the Crease Clinic of Psychological Medicine and Insondale Mental Hospital, and to the members of the nursing and dietary staffs.

MEPAZINE (PACATAL)¹—FURTHER REPORT

NORBERT BRUCKMAN, M.D., MURRAY KITCHENER, M.D., JOHN C. SAUNDERS, M.D.,
AND NATHAN S. KLINE, M.D.²

In July 1955 we (6) reported the results of a rapid evaluation of mepazine (Pacatal). The material had been supplied in bulk to an American pharmaceutical house from the German manufacturers and subsequently we had reason to believe that something happened somewhere along the line to introduce a contaminant. In a letter (5) to the editor of this journal in 1956 we stated that we were then re-evaluating the preparation. We did so in six different groups of chronic psychotics. The first group comprised 14 males all of whom had proved failures on electroshock, insulin, reserpine, chlorpromazine or some combination of these. This time we used mepazine manufactured in the United States (Warner-Chilcott's Pacatal). The patients were given 150 mgs. daily which was increased by 25 mgs. every 5 days until 300 mgs. was reached. This was continued for 2 months and then increased to 400 mgs. daily and continued for another 2 months. Despite the fact that these patients had failed on all previous therapies and were among the most chronic disturbed schizophrenics in the hospital, 6 of the 14 showed some improvement and it was specifically noted in several of the case records that in addition to becoming quieter and more cooperative depression was relieved. Improvement, however, was not sufficient for any of the patients to be considered for discharge. In contrast to our previous results, no side effects were noted in this group except transient drowsiness in one patient. We then expanded the study and tried 12 additional chronic psychotic males on a combination of 4 mgs. of reserpine and 200 mgs. of mepazine. Neither improvement nor side effects was noted in any patient in this group. On the combination of mepazine and chlorpromazine in another 12 male patients of the same extremely chronic therapy-resistant type with doses of 200 mgs. of mepazine and 400 mgs. of chlorpromazine 5

patients who had shown slight improvement on a combination of reserpine and chlorpromazine maintained their improvement and another 4 who were considered only slightly improved from the reserpine-chlorpromazine combination were now judged moderately improved. When these patients were subsequently maintained on chlorpromazine alone 1 of them relapsed to his previous condition and it was necessary to again add reserpine to reverse the picture. In this group also no side effects were noted.

At the same time 40 female patients of the same type were started on mepazine alone or in combination. Of 20 on mepazine alone, 1 was moderately improved, 6 slightly improved, and 13 unimproved. Of those on mepazine and chlorpromazine, 2 were moderately improved, 5 slightly improved and 3 unimproved. Of those on mepazine and reserpine, 1 was moderately improved, 5 slightly improved and 4 unimproved. There were no side effects in the mepazine-chlorpromazine group but 1 patient on mepazine alone complained of blurred vision and subsequently developed marked leucopenia which responded promptly to withdrawal of medication. Two of the patients on the mepazine-reserpine combination developed leucopenias and 1 of these had reactivation of an old osteomyelitis. The leucopenia progressed to agranulocytosis and subsequently the patient died. The other patient recovered uneventfully as did a third who developed a milder leucopenia.

There is little question that mepazine is an active ataractic agent and that at times it will bring about improvement when reserpine, chlorpromazine or the combination of these 2 drugs has proved ineffectual. We would recommend, as have other authors, that dosage be increased gradually to avoid side effects. The higher incidence of side reactions in the females on phenothiazine derivatives has also been commented on fairly frequently in the literature. Whether the combination of mepazine and chlorpromazine acted, in the females, to cancel out side ef-

¹ Appreciation is expressed to Warner-Chilcott Laboratories, Morris Plains, N. J., for the supply of Pacatal.

² Address: Rockland State Hospital, Orangeburg, N. Y.

fects or whether this was a statistical accident cannot be determined on the basis of the relatively small number of cases. Certainly this mepazine-chlorpromazine combination was the most effective one in both the males and females.

The expectation of finding a single ataractic agent that would be effective for all types of patients has not and is not likely to be realized. Rather we are having made available to us a sizeable number of pharmaceuticals which can be used selectively to meet the needs of the individual patient. On the basis of our experience with mepazine, not only in the hospital, but in private practice, and through information provided both in the literature and in conversation with numerous practicing psychiatrists, certain tentative conclusions can be drawn as to its use:

1. Of the ataractic agents presently available mepazine apparently induces the least depression and may even serve to relieve mild depressions when they pre-exist.

2. The incidence of blood dyscrasias in the females suggests that mepazine (along with the other phenothiazine derivatives) be used with considerable caution and under close medical supervision for the first month and a half. Patients should be told to report immediately any evidence of temperature elevation and "scratchy" or sore throat since these clinical symptoms usually appear early enough to prevent a serious blood dyscrasia by withdrawing medication. This limitation is set since no record of a blood dyscrasia occurring beyond the 45th day has been reported.

3. As noted first by Hiob and Hippius(3) and later by Bowes(1) (as well as in our own series) mepazine and chlorpromazine appeared to act synergistically.

4. The sympatholytic action of chlorpromazine and the parasympatholytic action of mepazine may also act to eliminate some of the side effects of each as has been reported by Kleinsorge(4) and by Braun(2) and confirmed in our own series.

5. It has been shown that whereas chlorpromazine blocks epinephrine and serotonin in various biological systems, mepazine does not. This may well be related to the absence of depression or the antidepressant activity of mepazine.

6. Mepazine, although potent, is somewhat milder in its effect than some of the other pharmaceuticals in this field. For this reason it particularly suggests itself for use in the office patient with agitation and depression or in those in whom the other pharmaceuticals have produced feelings of emptiness, depression or psychic discomfort.

SERUM LIPOPROTEIN CONCENTRATIONS IN A SCHIZOPHRENIC POPULATION¹

EDWARD H. STRISOWER, OLIVER DELALLA, JOHN W. GOFMAN, AND
BEVERLY STRISOWER

Whereas several hundred reports on serum lipids in schizophrenic patients have appeared

¹ This work was supported by a grant from the Albert and Mary Lasker Foundation, Inc. We wish to acknowledge the cooperation of the ward personnel at Stockton State Hospital and Napa State Hospital, California, and the assistance of Mrs. Bette Green, Maud Avery, and the technical work-

since 1912(1, 2) no information on serum lipoprotein concentrations is available to date. This report provides information on the distribution of both low and high density serum

esters at the Donner Laboratory in making this study.

² From the Division of Medical Physics of the Donner Laboratory of Medical Physics Radiation Laboratory, University of California, Berkeley, Cal.

TABLE 1

COMPARISON OF LOW DENSITY SERUM LIPOPROTEIN CONCENTRATIONS IN A NORMAL AND A SCHIZOPHRENIC MALE POPULATION

	n	Age	Serum Lipoprotein Concentrations*				MG/100ml of serum	
			mg/100ml of serum				Cholest*	n** Cholest
Schizophrenic	17	20-29	298 ± 62	39 ± 48	81 ± 31	39 ± 38	207 ± 30	168
Normal controls	335	20-29	326 ± 88	40 ± 21	75 ± 42	36 ± 39	209 ± 43

Normal controls	499	30-39	354 ± 84	51 ± 24	92 ± 55	51 ± 59	222 ± 44	
Schizophrenic	37	40-49	370 ± 81	45 ± 25	80 ± 37	46 ± 47	238 ± 43	84
Normal controls	249	40-49	382 ± 91	58 ± 23	108 ± 68	67 ± 97	239 ± 42	
Schizophrenic	14	50-69	402 ± 103	48 ± 19	86 ± 42	37 ± 30		
Normal controls	86	50-69	393 ± 76	58 ± 24	108 ± 54	61 ± 72		

* Mean values and standard deviation of the distribution.

** The normal group of males on which the cholesterol data are based is smaller than the entire normal control group for the serum lipoprotein data.

S_r⁰ refers to Svedberg units of flotation (10⁻¹³ cm/sec/dync/gram) including a correction to account for the self slowing of lipoproteins as their concentrations increase during the flotation process.

lipoproteins in a male schizophrenic population.

Serum lipoprotein and cholesterol determinations were performed by methods³ previously described(3, 4) on 88 male chronic schizophrenic hospitalized patients. Selection of these patients was based on the absence of other acute or chronic disease as judged by clinical criteria and routine laboratory tests; also, no patients who had received chemotherapy or electroshock treatments for several months preceding the blood sampling were included in this study. All blood samples were drawn in the morning 2-4 hours following breakfast.

Results are summarized in Tables 1 and 2

TABLE 2

COMPARISON OF HIGH DENSITY SERUM LIPOPROTEIN CONCENTRATIONS IN A NORMAL AND A SCHIZOPHRENIC MALE POPULATION

	n	Age	Serum Lipoprotein Concentrations* mg/100ml of serum		
			HDL ₁ ^{2**}	HDL ₂ ^{3**}	HDL ₃ ^{3**}
Schizophrenic ...	17	20-29	22 ± 5	38 ± 14	203 ± 15
Normal controls ..	335	20-29	23 ± 8	38 ± 30	218 ± 39
Schizophrenic ...	20	30-39	25 ± 7	57 ± 39	195 ± 37
Normal controls ..	499	30-39	24 ± 17	35 ± 27	222 ± 41
Schizophrenic ...	37	40-49	28 ± 17	58 ± 34	208 ± 45
Normal controls ..	249	40-49	26 ± 18	37 ± 29	228 ± 51
Schizophrenic ...	14	50-69	26 ± 60	39 ± 31	198 ± 46
Normal controls ..	86	50-69	28 ± 27	40 ± 33	219 ± 50

* Mean values and standard deviation of the distribution.

** HDL₁, HDL₂, and HDL₃, refers to high density serum lipoproteins defined by densities of 1.05, 1.075, and 1.145 gms/ml respectively.

³ We are indebted to Dr. Oliver deLalla for the development of the method and for the analyses of the high density serum lipoproteins.

for the low density and high density serum lipoproteins respectively. The tables provide mean values and standard deviations of the distribution for each serum lipoprotein class for a given age group for the schizophrenic population as well as directly comparable data for a normal population.

The schizophrenic population has, in general, low density serum lipoprotein and serum cholesterol concentrations similar to the matched normal population. The small differences seen in the direction of lower serum lipoprotein levels, most marked in the 30-39 year age group, are statistically not significant. Data on the three high density serum lipoprotein classes constituting the entire high density lipoprotein spectrum are presented in Table 2. No significant differences between the normal and schizophrenic populations exist, except for the following two instances. The HDL₂ lipoproteins are higher in the schizophrenic population in the 30-39 and 40-49 year age groups, significant at the 5 and 1 per cent levels respectively, and HDL₃ serum lipoproteins tend to be lower in the schizophrenic population at all age ranges studied; however this latter difference could be proven significant below the 5 per cent level only in the 30-39 year group. The biological and clinical significance of these observations is under further investigation at present.

The smaller standard deviations of the distribution obtained in most of our measurements on schizophrenic patients compared

with those of the normal population do not support the concept postulating a greater variability of serum lipid levels in schizophrenia (5-7). Furthermore, because of the much larger group of normal males on which the normal population statistics are based, lower rather than equal or higher standard deviations would be expected in the normal compared with the schizophrenic population.

Perhaps the most interesting and useful application of a knowledge of low density serum lipoprotein levels in a schizophrenic population relates to the question of cerebral atherosclerosis as an etiologic factor in schizophrenia. The highly significant correlation between the degree of coronary atherosclerosis and that of the major supply arteries of the brain, recently discovered (8), implies an important biochemical relationship between low density serum lipoprotein concentrations and cerebral atherosclerosis, similar to the well established association of coronary atherosclerosis with elevated low density serum lipoprotein levels (9-11). The lack of elevation observed in all classes of the low density serum lipoprotein spectrum and in all age groups of a schizophrenic population provides excellent biochemical evidence for

the view that cerebral atherosclerosis is not a significant etiologic factor in the schizophrenic reaction.

PROCEEDINGS OF THE AMERICAN PSYCHIATRIC ASSOCIATION

THE ONE HUNDRED AND THIRTEENTH ANNUAL MEETING, CHICAGO, ILLINOIS, 1957

The 113th annual meeting was held in Chicago, Ill. at the Morrison Hotel, May 13-17, 1957. The opening meeting, May 13, was called to order by the President, Dr. Francis J. Braceland, at 9:15 a.m. After the invocation by Rev. William J. Devlin, S. J., M. D. of Chicago, who is a member of the APA, welcoming remarks were presented by Dr. Roscoe Miller, M.D., Dean of the Northwestern University School of Medicine.

Dr. Braceland introduced President-Elect Dr. Harry C. Solomon, and then called for the reports to the membership. The Medical Director, Dr. Daniel Blain, read his 10th annual report reviewing the Central Office operations which have continued to expand during the past year. Dr. Matthew Ross, retiring Speaker of the Assembly of District Branches, related the history and development of the District Branch program. The Chairman of the Committee on Arrangements, Dr. Hugh T. Carmichael, called attention to the Convocation ceremonies scheduled for the following morning and also reported the diversionary program which had been arranged for members and guests in cooperation with the Ladies Committee under the Chairmanship of Mrs. L. Louis Steinberg. Dr. Titus Harris, Chairman of the Program Committee, pointed out new features of this annual meeting, including the Adolf Meyer Research Lecture and the Fellowship Lecture, formerly the Academic Lecture, to be presented in conjunction with the Convocation.

Dr. William Malamud, Secretary, reported the membership statistics for the past year. As of March 31, 1957 the total membership was 9,247. Dr. Jack R. Ewalt, Treasurer, presented his report which is included in another section of these Proceedings. He also informed the membership that in view of the limited financial reserve of the Association and its increasing expenses, the Council had

found it necessary to recommend that the dues for Fellows and Members, be raised effective April 1, 1958.

Dr. Theodore Lidz, Chairman of the Hofheimer Prize Board, presented this Prize for research in psychiatry to Christoph M. Heinicke, Ph.D., of Portland, Oregon for his work at the Tavistock Clinic in London, England. The prize-winning study dealt with the effects of separating two-year olds from their parents. Honorable Mention was given to Dr. Charles Shagass of Montreal, Canada. Dr. Frank J. Curran, Chairman of the Board of the Isaac Ray Award, presented the Award to Dr. Manfred S. Guttmacher, psychiatrist and Chief Medical Officer of the Supreme Bench of Baltimore, Maryland. The Isaac Ray Award is presented for outstanding contributions to better understanding between psychiatry and law. Dr. Guttmacher will deliver his series of lectures under the sponsorship of the Schools of Law and Medicine at the University of Minnesota in the academic year 1957-1958, and the lectures will be published by Farrar, Straus and Cudahy. The winners of the Mental Hospital Achievement Awards were announced by Dr. Blain as the Saskatchewan Hospital, Weyburn, Canada, and the Receiving Hospital, Detroit, Michigan. Honorable Mention Awards were won by the Northern State Hospital, Sedro-Woolley, Washington, and the Madison State Hospital, Indiana. These Awards will be presented at the Mental Hospital Institute in the fall.

Dr. Braceland introduced the recommendations of the Membership Committee, as approved by the Council, regarding applications for election to membership and for changes of membership status. On motion, duly seconded, the recommendations were approved by the membership. There were 657 new members elected bringing the total to 9,904.

Dr. Braceland was introduced by Dr. Solomon and gave his Presidential Address entitled "Psychiatry and the Science of Men." Dr. Solomon responded, and then the audience was asked to stand in memorial to the members of the Association who had died during the year. The benediction was pronounced by the Rev. Donald Cox, Chaplain of Kankakee (Illinois) State Hospital.

On Monday evening, May 13, the 1st annual Adolf Meyer Research Lecture was presented by Stig Akerfeldt, Ph.D., of the Nobel Institute in Stockholm, Sweden, on the subject "Serological Reaction of Psychiatric Patients to *n,n*,dimethyl phenylamine." Dr. Nathan S. Kline, Chairman of the Research Committee, moderated a discussion panel following the address. This Lecture is planned as a means of bringing an outstanding foreign researcher to each annual meeting to present a scientific paper.

The next business session was called to order by the President on Tuesday morning, May 14, at 9:00. Dr. Robert S. Garber, a member of the Board of Tellers for Election of Officers, presented his report. A total of 4,398 ballots were cast, with 28 being declared invalid. The officers elected for 1957-1958 are as follows: Dr. Francis J. Gerty, President-Elect; Dr. William Malamud, Secretary; Dr. Jack R. Ewalt, Treasurer; Incoming Councillors—Dr. C. H. Hardin Branch, Dr. Addison M. Duval, and Dr. Jacques S. Gottlieb. Regarding the proposed amendment to the Constitution and By-Laws to establish 2 new elective offices (Vice Presidents), both portions were approved by the following figures: Amendment to Constitution—3,755, yes; 146, no; 48 invalid; Amendment to By-Laws—3,752, yes; 146, no; and 48 invalid. The Parliamentarian, Dr. Henry Davidson, then read 2 new proposals for amending the Constitution and By-Laws which had been approved by the Council. The first dealt with the adjudication of ethical grievances, and the second with the announcement of APA election results in the JOURNAL. These proposals will be published in the JOURNAL and will appear on the next mail ballot for consideration by the membership.

Reports were presented by the Coordinating Committee Chairmen who reviewed the

activities and plans for their respective Standing Committees: On Technical Aspects of Psychiatry, Dr. Frank J. Curran; On Professional Standards, Dr. Wilfred Bloomberg; and On Community Aspects of Psychiatry, Dr. William C. Menninger. This concluded the business session, and there was a short recess before the Convocation.

Dr. Braceland presided at the Convocation for the newly elected Fellows, which got underway at 10:00 a.m. in the Terrace Casino, and Dr. Hugh T. Carmichael served as Grand Marshall. The program began with a Processional March by the Convocation participants accompanied by an electric organ. The Life Fellows were seated to the left of the rostrum and the newly elected Fellows to the right. The invocation was given by Dr. Edgar Siskin, North Shore Congregation Israel, Glencoe, Ill. The Convocation Ceremony was very impressive and included a reading of the objectives of the APA and of Fellowship in the Association, and the official welcome to Fellowship by the President. Dr. Solomon introduced the Fellowship Lecturer, Dr. Gregory Zilboorg, who spoke on "Eugen Bleuler and Present Day Psychiatry." Dr. E. Eduardo Krapf of Geneva, Switzerland, gave the responses. The Recessional March followed the benediction by the Rev. Edward P. Dixon, Chaplain of Cook County Hospital, Chicago.

The business meeting on Wednesday morning, May 15, was called to order by the President at 9:30. The Secretary reported the actions of the Council during the past year, and these matters were duly approved by the membership upon proper motion from the floor. Separate motions were approved authorizing San Francisco, California, as the site for the 1958 annual meeting; Greater Miami Society of Psychiatry and Neurology as an Affiliate Society; and the establishment of the following District Branches: Hawaii Psychiatric Society, Illinois Psychiatric Society, Iowa District Branch, New York State Capital District Branch, South Carolina District Branch, and Wisconsin Psychiatric Association, Inc. The presentation of Certificates by the Secretary to those retiring from office was the last item of business at this meeting.

The Annual Dinner was held on Wednesday evening, May 15, and was well attended. The Past-President's Medal was presented to Dr. Francis J. Braceland by Dr. Kenneth E. Appel. A handsome Illuminated Address and an inscribed silver bowl were awarded to Mr. Austin M. Davies as a tribute to his 25 years of dedicated service to the Association as Executive Assistant and Business Manager of the JOURNAL. The latter presentation was made by Dr. Clarence B. Farrar, who has been closely associated with Mr. Davies as Editor of the JOURNAL for the past quarter of a century. A special greeting and plaque were also presented to President Braceland on behalf of the Governor of Illinois by Dr. Francis J. Gerty, incoming President-elect.

The final business session was held on Friday, May 17, at 9:00 a.m. with Dr. Braceland presiding. The Secretary reported the actions of the Council at its meeting on May 16, and these matters were approved by the membership. By separate motions the Western New York Psychiatric Society was approved as a District Branch and a revised constitution for the Connecticut District Branch also approved. Statistics regarding the enrollment at the 113th Annual Meeting were reported by the Secretary as follows: 1,924 members, 953 nonmembers, 523 guests (ladies, white cards), 137 complimentary and 199 exhibitors, for a total enrollment of 3,736. Dr. Daniel Blain presented to the Association a small wooden box, hand-carved from a single block of Australian Fiddleback Blackwood, which was a gift from Dr. Guy Springthorpe of the Australasian Association of Psychiatry (Australia and New Zealand) for use in the APA Home. Dr. Braceland then presented to Dr. Solomon the gavel signifying his assuming the Presidency. As there was no further business, the session was adjourned. The 113th Annual Meeting was officially closed at 5:00 p.m. on May 17.

RESOLUTIONS

The following Resolutions were submitted by Dr. James H. Wall, Chairman of the Committee on Resolutions:

WHEREAS, the American Psychiatric Association has conducted its 113th Annual Meeting in the City of Chicago in 1957.

1. *Now Therefore Be It Resolved*, That The American Psychiatric Association express its appreciation to Dr. Roscoe Miller, Dean of Northwestern University School of Medicine, for his cordial welcome to this association.

2. *Be It Further Resolved*, That the Association does hereby record its very real appreciation to its beloved President, Francis J. Braceland, for his able leadership by which he has guided the membership and the affairs of the Association throughout the past year and especially for his successful efforts to interpret to the membership and to the country at large, the Association's programs and policies.

3. *Be It Further Resolved*, That the Association expresses its thanks to the Officers, Members of Council, Officers of Assembly, and to the Section and Committee Chairmen and Secretaries for the very able manner in which they have pursued their duties making possible the successful and smooth functioning of the Association throughout the year and particularly during the 113th Annual Meeting.

4. *Be It Further Resolved*, That the Association acknowledges its great debt of gratitude to Dr. Daniel Blain and to Mr. Austin Davies for their very conscientious and untiring services on our behalf and to their loyal staffs whose labors ensure the perfect functioning of the Association's business.

5. *Be It Further Resolved*, That the Association again record its profound debt of gratitude to Dr. Clarence B. Farrar for his most successful work as Editor of the American Journal of Psychiatry, and for his constant efforts to maintain the high ideals of the profession of psychiatry.

6. *Be It Further Resolved*, That the Association hereby expresses its appreciation to the members of the Press, who over the year and especially at the Annual Meeting, have so well interpreted the aims, ideals and accomplishments of our profession to the American people and to the world.

7. *Be It Further Resolved*, That the Association extend its gratitude to the Committee on Arrangements and to its Chairman, Dr. Hugh T. Carmichael, and those associated with him, for the hospitality that we have experienced during our meeting in this city, the hospitality which has made our meeting pleasant and successful.

8. *Be It Further Resolved*, That the Association hereby conveys its sincere appreciation to the Ladies Committee and to its Chairman, Mrs. D. Louis Stenberg, and those associated with her, in providing entertainment for the wives of the members of the Association.

9. *Be It Further Resolved*, That the Association express its profound appreciation to the Committee on Program and especially to its Chairman, Dr. T. H. Harris who have provided a most interesting and informative program and particularly for the distinguished foreign visitors who appeared on the program.

10. *Be It Further Resolved*, That the Gratitude of the Association also be expressed to the Budget Committee and the Chairmanship of Dr. Robert H. Felix for their careful budgeting of the funds of the Association.

11. *Be It Further Resolved*, That the Association likewise expresses its appreciation to the Committee on Public Information and to its Chairman, Dr. Robert Morse, for their successful efforts to develop a better public understanding of psychiatry and the problems which it encounters and seeks to overcome.

12. *And Be It Further Resolved*, That the Association expresses its deep appreciation of the skillful, tireless efforts on the part of Mr. Robert L. Robinson, who has consistently and diplomatically worked with the Press in maintaining the high standards of public relations of the Association.

SUMMARY OF MEETINGS OF COUNCIL AND EXECUTIVE COMMITTEE

MAY 1956 TO MAY 1957

This report presents in summary form the principal actions of the Council and the Executive Committee at meetings held throughout the year. Many routine matters, such as referrals to Committees prior to definitive action, are not included. Copies of the full minutes have been forwarded to the officers of each District Branch and Affiliate Society following the various meetings to keep their members informed of the matters that were considered and the action that resulted.

Executive Committee Meetings, June 16 and September 15, 1956.—Accepted the invitation of the National Research Council to act as a joint sponsor for a Conference on Pharmacotherapy in Washington, D. C. during September 1956 and directed Drs. Jacques S. Gottlieb and Milton Greenblatt to continue to represent the APA in its relations with the N.R.C. Received a Resolution from the National Association of Private Psychiatric Hospitals regarding the operations of the Central Inspection Board and directed the Secretary to inform them that negotiations were underway with the Joint Commission on Accreditation of Hospitals and that they would be kept informed of developments. Accepted the details as recommended by the Medical Director for the previously approved extension to the Information Service. Approved a statement on tranquilizing drugs prepared jointly by the Committees on Research, Therapy, and Public Information. Recommended that in announcements of the results of APA elections, only the names of successful candidates should be indicated, without any designation of the number of votes received by the respective candidates. Directed payment of the annual APA dues to the World Federation for Mental Health. Directed that the Society of Neurology and Psychiatry of Hawaii should be referred to appropriate West Coast District Branches for assistance in setting up a Regional Research Meeting in Honolulu to supplement the APA Annual Meeting in 1958. Authorized publication and distribution in the *Mind Patch* at APA expense of a one page notice about the Second International Congress of Psychiatry. Authorized the Medical Director to employ part-time help to handle the distribution of APA publications and to charge the salary against the Publications Revolving Fund in an amount not to exceed \$1,000 per year. Directed that all matters involving representation or delegation to international meetings should be referred to the Committee on International Relations

for comment and recommendations prior to official action by the President or the Executive Committee. Authorized the House Committee to obtain estimates and plans including air conditioning for the renovation of the APA Home and to present their recommendations for consideration by the Council. Directed that an appropriate scroll should be prepared for presentation at the fall 1956 meeting of the Council and Committees to Dr. William Rush Dunton, Jr., in recognition of his years of service with the American Journal of Psychiatry. Disapproved a proposed questionnaire and reference service on sources of support for research projects as presented by the Committee on Research. Authorized the Public Information Committee to seek funds to finance a second conference similar to the Swampscott Conference. In accordance with the policy previously approved by the Council, authorized the Public Information Committee and the Medical Director, in consultation with the APA Legal Counsel, to complete negotiations for a television contract with the Sudan Company, Inc., with terms similar to those of the previous television contract. Directed that the Archives of Neurology and Psychiatry be informed that papers to which the APA has reserved publication rights are frequently released for publication in other journals upon request to the Editor of the JOURNAL by the author, and that the APA Divisional Meetings are considered to be a particularly promising source of material. Disapproved an application for change of name by the Section on Convulsive Disorders because the terms proposed for use in the new name were incompatible, and suggested that a more satisfactory designation be presented for consideration.

Council Meeting, October 27-28, 1956.—Directed that the Committee on Resolutions be discharged following the 1957 Annual Meeting and instructed the Committee on Arrangements to assume the functions of this Committee at that time. Authorized the Executive Assistant to consider all proposals in the matter of a new APA Biographical Directory and to approve a contract for its publication. Approved Atlantic City, N. J. as the site for the 1960 Annual Meeting during the second week of May. Authorized the Central Inspection Board to approach private foundations in the name of the APA seeking funds to finance inspections of private hospitals and re-inspections of hospitals previously approved or conditionally approved, after the de-

tails in the matter had been worked out in collaboration with the Medical Director's Office. Approved in principle the holding of a workshop on the use of psychoanalysts in training programs at public psychiatric hospitals with the proviso that the necessary schedule arrangements are completed by the Committee on Education in Public Hospitals in collaboration with the Medical Director's Office and funds sufficient to finance such a meeting are raised outside the APA. Recommended to the membership the establishment of the Iowa District Branch. Received the statement on desegregation prepared by the Committee on Academic Education. Approved a recommendation from the Committee on International Relations for the translation of outstanding foreign psychiatric books into English. Approved in principle a recommendation by the Public Information Committee that the practice of photographing or televising of actual psychiatric patients be optional at the discretion of the patient, his family, his physician, and the hospital. Approved recommendations by the Committee on Veterans for two letters over the President's signature to the Veterans Administration suggesting that immediate consideration be given to bringing VA professional salaries in line with parallel groups in non-Federal hospitals and suggesting that consideration be given to the "turnover rate" as well as the average daily patient load in formulating the budget for individual VA hospitals. Confirmed the President's authority to appoint official APA representatives to foreign organizations and international meetings without expense to the Association. Interpreted its previous policy regarding acceptance of APA members into District Branches to mean that if a District Branch objects to admitting an established APA member who is geographically qualified and notifies the Council of its reasons, the rejection stands unless the Council takes contrary action. Council also indicated that it was taking this matter under advisement and would endeavor to correct the problem. Approved the employment of the Thomas E. Burke and Company firm from New York City to audit the APA accounts. Directed that the membership dues for Dr. Florence Nichols should be remitted during the term of her work in India. Directed that a communication should be sent to the Speaker of the U. S. House of Representatives and to the appropriate Congressional Committee indicating the loss felt by the APA due to the death of Representative Percy Priest. Recommended to the Assembly the formation of a legislative committee in each District Branch. Authorized the formation of a Standing Committee on Disaster and Civil Defense and assigned it to the Coordinating Committee on Community Aspects of Psychiatry. Approved a recommendation by the Long Term Policy Commission that there should be no change at present in the size of the Research Committee. Authorized the formation of a Standing Committee on Mental Deficiency and assigned it to the Coordinating Committee on Technical Aspects of Psychiatry. Approved APA membership in the National Citizens Committee

for Support of the World Health Organization and directed that the dues should be charged against the Council Contingency Fund. Approved a proposed mental hospital procurement study to be made for the Mental Hospital Service by a medical marketing research firm and authorized the Medical Director to seek outside funds to finance the study. Disapproved a Resolution from the Committee on Medical Education that residents should not be permitted to do private practice until they had completed three full years of psychiatric training. Authorized the APA to act as a co-sponsor with the Psychopharmacology Center of the National Institute for Mental Health in a conference on psychopharmacology at no expense to the APA. Authorized the Committee on Public Health to co-sponsor a panel at the November 1956 meeting of the American Public Health Association. Approved the plan proposed by the Committee on Public Health for final disposition of the material compiled in the Committee's survey on the relationship between infectious diseases and mental deficiency. Approved a request from the Committee on Private Practice to conduct a survey among the APA membership on the practice of charging fees to doctors and their dependents by distributing a questionnaire through the *Mail Pouch* with the costs to be charged to the Committee budget. Recommended to the membership the rejection of requests for the establishment of Sections on Carbon Dioxide Therapy and Group Psychotherapy. Directed that in accordance with established APA policy the JOURNAL should not accept for publication an announcement regarding the training of psychotherapists by the American Academy of Psychotherapists.

Executive Committee Meetings, January 5 and March 9, 1957.—Approved regulations to govern the acceptance of gifts, fellowships, awards and grants to the APA, presented by the Committee on Grants and Awards. Approved recommendations by the Committee on Therapy for amplification of the APA Standards for Electro-shock Treatment, provided the phraseology was satisfactory to the Legal Counsel. Approved a request from the Committee on Research for authority to publish additional psychiatric research material as funds become available. Approved a \$300 appropriation to pay the expenses of a guest speaker to the 1957 Annual Meeting, on request by the Committee on Program, and directed that it should be charged to the Annual Meeting expenses. Directed the Chairman of the Coordinating Committee on Technical Aspects of Psychiatry to review and edit the Proceedings of the Philadelphia Regional Research Conference prior to publication. Approved a contract with the Mutual of New York Insurance Company to cover personnel retirement and insurance in accordance with an October 1956 directive of the Council. Approved the solicitation of funds from appropriate sources to conduct a study on the ways in which tranquilizing drugs are affecting the use of nursing and other ward personnel in mental hospitals. Approved the solicitation of funds from

appropriate sources to implement the recommendations of the Ad Hoc Committee in Liaison with the American Academy of General Practice which were approved by the Council in October 1956. Approved the solicitation of funds from appropriate sources to survey the current quantitative use of tranquilizing drugs in mental hospitals, and professional judgments of their effect on patients, hospital programs, and related matter. Changed the schedule for the 1957 fall Committee Meetings to October 24-26 in Washington, D. C. Recommended that the 1957 fall Council Meeting be scheduled on November 22-23 at a site to be determined by the Incoming President. (This date has subsequently been changed to November 23-24.) Recommended to the Council that the Editor of the JOURNAL be instructed to publish annually the reports of the Coordinating Committee Chairman which contain summaries of Committee activities, and that the Coordinating Committee Chairmen be instructed to recommend publication of individual Committee reports which seem to merit general dissemination. Directed that the *Mail Pouch* follow the regulations established for the JOURNAL to govern the acceptance of advertising material. Recommended to the membership the approval of an application from the Greater Miami Society of Psychiatry and Neurology for Affiliate Society status. Approved the annual presentation of a personal gift to the Academic Lecturer at the Mental Hospital Institute, with the expense to be charged to the Institute budget. Approved in principle the scheduling of a Mental Hospital Institute in Canada. Directed the Medical Director to review the APA arrangement with the Mental Health Materials Center and to continue the affiliation on the best available terms. Approved co-sponsorship by the APA with the National League for Nursing of a psychiatric aide teacher-training program as recommended by the Committee on Psychiatric Nursing. Approved the recommendation of the Committee on Public Information regarding a proposed public relations motion picture on psychiatry and authorized the Committee to proceed with negotiations in the matter with the proviso that the film have APA sponsorship. Directed that there should be no change at the present time in the name of the Committee on Legal Aspects of Psychiatry. Directed that APA personnel temporarily employed through grants should be included in the retirement-insurance program when they otherwise meet the requirements established for regular employees. Authorized the Treasurer to pay the expenses for the personnel retirement-insurance program on an annual basis. Approved the establishment of a lectureship at Annual Meeting to be known as the Adolf Meyer Research Lecture and designated the Committee on Research to handle the arrangements. Directed that when the Medical Director or others authorized through his office make application for funds from grants, they should submit to the Executive Committee, via the Treasurer, a detailed budget and that no expenditures be authorized against these funds until the budget has been approved.

Authorized the amending of several budgets for both the 1956-1957 and 1957-1958 budget years with funds received from outside the Association. Directed the Secretary to draft a letter to Mr. Clarkson Hill expressing the appreciation of the Council for his analysis of the APA business practices. Authorized the Medical Director to investigate the possibility of the APA's becoming an additional co-sponsor of Mental Health Week. Approved an official Certificate of District Branch Status to be prepared upon request from such societies, to bear the signature of the Secretary, and to be embossed with the official Seal of the APA. Approved a Divisional Meeting at Miami Beach, Florida on December 1-3, 1958. Empowered the Medical Director's Office to sign an agreement with the U. S. Navy to arrange editorial services. Directed the Committee on Relations with Psychology to seek additional legal advice on the matter of interpretation of certification for psychologists.

Council Meeting, May 11-12 and 16, 1957.—Did not approve a request for Affiliate Society status from the Association for Advancement of Psychoanalysis because the applicant society does not meet the requirements of the By-Laws. Directed that certification by recognized, duly constituted bodies should not be a mandatory requirement for Fellowship but that such information should be utilized along with other data in the determination of the general qualifications of applicants. Established an Ad Hoc Committee to be comprised of former officers of the Association to consider the integration of the work of officers with that of the Central Office staff and to suggest the prerogatives and general responsibilities of the officers. Directed that the Coordinating Committee Chairmen should constitute an Ad Hoc Committee with a comparable group appointed by the Assembly to foster the efficient growth of the Committee structure of the District Branches and the integration of their work with that of the general Committee structure of the APA. Directed that Ad Hoc Committees should be assigned to appropriate Coordinating Committees when feasible. Directed that Ad Hoc Committees must have been in operation for at least two full years before becoming eligible for consideration for conversion into Standing Committees. Directed that a Committee on Committees comprised of the Coordinating Committee Chairmen should be set up to evaluate requests for new Committees, to review constantly the established Committees, and to maintain a roster of personnel resources which can be used by the President in setting up new Committees. Approved in principle the reorganization of several Central Office programs, which provide services to hospitals, into a single administrative division to utilize to better advantage the available personnel. Approved a renovation plan for the APA Home which authorized a total of \$172,000 for this purpose. Directed that the list of deceased members should not be publicly read from the rostrum during the Annual Meeting business sessions but should be suitably honored by some other means. Authorized the formation of a Standing Committee in Liaison

with the American Hospital Association and assigned it to the Coordinating Committee on Professional Standards. Approved a proposed amendment to the Constitution and By-Laws regarding the adjudication of ethical grievances; also approved a proposed amendment to the By-Laws dealing with the publication of APA election results in the JOURNAL and directed that both proposals should be presented to the membership for consideration by mail ballot. Approved a budget for the Conference on Volunteers for the 1957-1958 budget year. Did not approve a request for establishment of a Committee on Social Psychiatry because the Committee on Therapy already encompasses this area. Authorized the awarding of a certificate to Dr. William Menninger in recognition of his continued efforts to obtain increased appropriations from various State legislatures to finance improvements in their respective mental health programs. Received a Resolution from the National Association of Private Psychiatric Hospitals regarding the Central Inspection Board. Suggested that the Incoming President appoint an Ad Hoc Committee to review the work and value of the Central Inspection Board and to investigate the possibility of its becoming a member of the Joint Commission on Accreditation of Hospitals. Directed that future contracts for inspections by the C.I.B. should be approved by the Treasurer as adequate to cover the projected expenses before they are signed. Authorized publication of the C.I.B.-Joint Commission on Accreditation of Hospitals statement regarding the dissolution of their agreement for the inspection of psychiatric hospitals by the C.I.B. Approved a commendation by the C.I.B. to President Braceland for his efforts in obtaining a modification of the original statement in this matter which had been scheduled for release by the Joint Commission. Authorized the negotiation of a 20-year mortgage to raise the \$100,000 needed as additional funds to finance the renovations to the APA Home and authorized the President, Secretary, and Treasurer to negotiate and sign such a mortgage on behalf of the Association. Directed an increase of the annual membership dues, effective April 1, 1958, to \$45 for Fellows and to \$30 for Members, with the dues for Associate Members remaining at \$10. However, after five years as an Associate Member, such dues will automatically be increased to the same level as Members. Recommended to the membership the establishment of the following District Branches: Hawaii Psychiatric Society, Illinois Psychiatric Society, New York State Capital District Branch, South Carolina District Branch, Western New York Psychiatric Society, and Wisconsin Psychiatric Association, Inc. Commended Dr. Mathew Ross, retiring Speaker of the Assembly of District Branches, for his efforts in stimulating the development of the District Branch movement, and the vigorous manner in which he conducted the affairs of the Assembly during the past year. Elected Dr. Francis J. Braceland as Moderator. Elected Dr. Braceland and Dr. Howard P. Rome to serve on the Executive Committee. Approved

a new Procedural Code for the Assembly of District Branches. Recommended to the membership the approval of a revised Constitution for the Connecticut District Branch. Changed the name of the Hawaii Regional Research Conference to the Hawaii Divisional Meeting. Approved a recommendation from the Ad Hoc Committee on District Branch Committees which directed the Chairmen of Standing Committees which belong to Coordinating Committees to keep open and free communication with the liaison representatives of the District Branches. This was set up as a pilot plan. Directed that no action be taken at that time regarding the possibility of extending an invitation to hold the next International Congress of Psychiatry in the United States in 1961, but indicated that the Executive Committee could reconsider the matter. Authorized the Committee on Certification of Mental Hospital Administrators to seek funds to sponsor a two-day conference with the American Hospital Association to study the qualifications necessary for mental hospital administrators. Interpreted the previous action authorizing the Adolf Meyer Research Lecture at Annual Meetings to mean although the Research Committee can submit recommendations to the Program Committee for the choice of the lecturer, the final decision and authority for the arrangements rest with the Program Committee. Approved the principle embodied in a joint report prepared by the Committees on Child Psychiatry and Medical Education regarding the desirability of incorporating, where feasible, child psychiatry training into the preparation of residents in general psychiatry, but emphasized that the manner in which this principle should be applied must be left to the individual training centers. Approved a request from the Committee on Rehabilitation for a formal representation to the proper authority suggesting a change of name for the "President's Committee on Employment of the Physically Handicapped" which will not specifically exclude the mentally handicapped. Authorized the Chairman of the Committee on Public Health to serve as the representative of the APA on a Technical Committee of the Mental Health Section of the American Public Health Association. Accepted the reaffirmation of the State Surveys Program submitted by the Committee on Public Health. Approved a Resolution to the Secretary of Defense suggesting that the **Armed Forces Medicare Program** be extended to include treatment of mental illness. Approved the recommendations of the Incoming President for appointments to the Membership Committee. Approved the continuance of the following Ad Hoc Committees: (1) On Education in Public Hospitals in Liaison with the American Psychoanalytic Association, assigned to the Coordinating Committee on Technical Aspects of Psychiatry; (2) Increasing Responsibility of the APA, designated an independent Committee; (3) Mental Hospitals, assigned to the Coordinating Committee on Professional Standards; (4) In Liaison with the American Academy of General Practice, assigned to the Co-

ordinating Committee on Professional Standards; and (5) Religion and Psychiatry, assigned to the Coordinating Committee on Community Aspects of Psychiatry. Authorized the Medical Director to

sign a contract with a construction firm for the renovation of the APA Home.

WILLIAM MALAMUD, M. D.,
Secretary

TREASURER'S REPORT: AMERICAN PSYCHIATRIC ASSOCIATION

May 13, 1957

The activities of the Association continued to expand during this year.

Total income for the year was.... 658,455.66

Total expenditures..... \$719,133.34

While this totals an excess of expenditures over income of \$60,677.68, it includes figures for payments on pledges to the building fund, and payments on grants, scholarships, and awards from the restricted funds, neither of which can be legitimately considered part of our routine operations. However, these two items approximately offset and if we correct for them the actual operations show our income to be \$59,006.88 less than our expenditures.

The members are perhaps interested in the reasons for the deficit in this year. The auditor's report is available and I would be glad to show it to anyone interested. In summary, the principal reasons for the deficit operations are the fact that the Central Inspection Board, which was expected to be approximately self supporting, in fact, brought in \$37,031.75 less than it spent, and the state surveys which last year showed a profit, partially due to a grant, this year showed expenditures of \$37,723.98 in excess of the income, the deficit offset by carry over from the grant of last year. The Mental Hospital Service which is usually self supporting, this year showed \$9,003.26 more expenditure than income. The American Journal of Psychiatry which costs more than \$100,000 per year to publish and distribute produces income making it necessary to divert only \$27,000 per year from the membership dues. Due to a slight increase in size this year and a special issue, the JOURNAL account exceeded the \$27,000 subsidy from the membership account by just over \$4,000.

Partially offsetting these operations were decreased expenditures by committees and Council and in the Medical Director's and Executive Assistant's offices.

Because our total reserve, excluding the value of the building, is only a little more than \$100,000 it is obvious that we must discontinue some activities in the coming year or immediate measures must be taken to increase the income of the Association. Our present payroll is \$459,758.60 per year.

During this budget year, starting April 1st, additional expenditures to the Association will be made for the retirement and insurance fund for the employees. The annual cost to the Association will be \$17,020. This brings personnel costs to \$276,778.60 per year. In addition, the French have moved from our building and the income from the rent on the new home will not be collected during this year and we must pay rent for quarters in Washington pending the renovation of the building so that it can be occupied by the Washington offices of the Association. This means that during this year the cost of maintenance, insurance and taxes of the new home will be added to our usual expense for rent in Washington with no offsetting income in revenue from rent of the new home.

The members must give serious thought to decisions concerning our financial picture which have been too long postponed. Our scale of operations must be reduced or our sources of income must be expanded. In the past year we have used approximately one-half of our reserves and the coming year will see their total depletion if drastic steps are not taken immediately. This information has been made known to Council and appropriate steps have been taken.

1. First tighter budget controls that the budget committee have recommended for some years have been authorized and we will have quarterly audits rather than annual audits so that the Treasurer and the members can be better informed as to the trends of our financial operations.

2. Some activities are being curtailed.

3. To help your Association's income and to help you with your income tax deductions, Council has increased the dues to the following rates:

Associate Members: ..\$10.00 per year for 5 years.
Then \$30.00 per year.

Members:\$30.00 per year.

Fellows:\$45.00 per year.

This new income should greatly help our financial situation.

JACK R. EWALT, M. D.,
Treasurer

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.

In conformance with the request of The American Psychiatric Association, the American Neurological Association, and the American Medical Association, we are submitting the following account of the activities of the American Board of Psychiatry and Neurology, Inc., since the last report to the Associations by letter dated March 22, 1956.

The Board consists at present of the following members:

Appointed by the American Psychiatric Association:

Dr. David A. Boyd, Jr. (term of office expires December, 1959)

Dr. C. H. Hardin Branch (term of office expires December, 1958)

Dr. Henry W. Brosin (term of office expires December, 1957)

Dr. William Malamud (term of office expires December, 1960)

Appointed by the American Neurological Association:

Dr. Harvey Bartle, Jr. (term of office expires December, 1959)

Dr. Knox H. Finley (term of office expires December, 1957)

Dr. Francis M. Forster (term of office expires December, 1960)

Dr. Paul I. Yakovlev (term of office expires December, 1958)

Appointed by the American Medical Association:

Dr. Russell N. DeJong (term of office expires December, 1958)

Dr. L. M. Eaton (term of office expires December, 1960)

Dr. Francis J. Gerty (term of office expires December, 1959)

Dr. George N. Raines (term of office expires December, 1957)

At the annual meeting of the Board in December, 1956, the following officers were elected:

Dr. George N. Raines, President

Dr. Paul I. Yakovlev, Vice-President

Dr. David A. Boyd, Jr., Secretary-Treasurer

The annual meeting of the Board was held in New York City in December, 1956. At this time, 266 candidates were examined by the Board. Of this number, 144 were certified in Psychiatry, 12 in Neurology and none in Neurology and Psychiatry.

When the Board met in New Orleans, La., March, 1957, 205 candidates were examined. Of this number, the Board certified 115 in Psychiatry and 13 in Neurology, and none in Neurology and Psychiatry.

Since its inception, the Board has received 8,261 applications. Some of these are still under consideration. The total number of diplomas issued by the Board to date is 5,885. Of this number, 4,524 are certified in Psychiatry 389 in Neurology, and 972 in Neurology and Psychiatry.

DAVID A. BOYD, JR., M.D.,
Secretary-Treasurer

TO AESCULAPIUS

With Aesculapius, the physician,
That cures all sickness, and was Phoebus' son,
My Muse makes entry; to whose life gave yield
Divine Coronis in the Dorian field
(King Phlegius' daughter), who much joy on men
Conferr'd, in dear ease of their irksome pain.
For which, my salutation, worthy king,
And vows to thee paid, ever when I sing.

—HOMER

(Hymn to Aesculapius,
George Chapman, trans.)

OFFICIAL NOTICE

AMERICAN PSYCHIATRIC ASSOCIATION OFFICIAL BALLOT FOR VOTING ON PROPOSED AMENDMENTS 1958

Proposition No. 1

This is a proposal to amend the Constitution by giving the Council authority to reprimand, or admonish a member, or for a limited period, suspend him from the privileges of membership for certain unethical practices of behavior. The specific offenses are detailed in proposition no. 2. The following would provide Council with the Constitutional authority to initiate disciplinary action.

(1) Article VII of the Constitution is amended by adding thereto a new section to be designated section 9, reading as follows:

9. Council shall have the power to direct the President to admonish or reprimand a member whenever such action is authorized by a two-thirds vote of the Council, and when by a two-thirds vote of the Council such action is determined to be in the best interests of the Association. The Council shall have power to suspend a member from the privileges of membership whenever the Council by a two-thirds vote determines that such action would be in the best interests of the Association. Such suspension, however, shall be for a period not in excess of one year, and may be for a lesser period.

Proposition Number 2

This makes the changes in the by-laws necessary to implement proposition 1. It would be inconsistent to vote "yes" on proposition 1 and "no" on proposition 2 or *vice versa*. The changes in the by-laws proposed below also spell out the procedure to protect the rights of the members concerned.

(2) ARTICLE III of the By-Laws is amended as follows:

The title of the Article is changed from RESIGNATION AND DISMISSAL to RESIGNATION AND DISCIPLINARY ACTIONS.

In section 2 of this Article, the first "shall" is changed to "may," so that section 2, as amended, opens with the following words:

"2. The name of any member declared unfit for membership by a two-thirds vote of the members of the Council present at any annual meeting of that body may be presented by the Council to the Association" . . . (continuing as before.)

The following sections are now added to Article III of the By-Laws:

3. A member may be admonished, reprimanded, expelled or suspended from the privileges of membership if such action is determined and voted by two-thirds of the Council; provided Council by a two-thirds vote shall determine that such member has been engaged in unethical or unprofessional conduct, or has wilfully refused to comply with resolutions or requests of the Council, or brings discredit or dishonor on the Association or on the practice of psychiatry or if he has been convicted of a crime involving moral turpitude.

4. An Ethics Committee is hereby created consisting of six Fellows, one or two of whom shall be past Presidents of the Association. The terms of each member shall be so adjusted that each year two seats will become vacant, and in each succeeding year the incoming President will appoint members to fill the two ensuing vacancies on the Committee.

The President will designate from the membership of the Committee a Chairman, and the term of the chairman shall be for a period of one year. Succeeding Chairmen shall likewise be appointed by the President. Vacancies developing during the term of any member of the Committee will be filled by designation of the President who will name an *ad interim* member or Chairman for the unexpired portion of the term of each person whose seat had become vacant.

5. All instances of behavior denounced in Section 3 of this Article, and reported to the Secretary of the Association, will be referred by the Secretary to the Ethics Committee.

This Committee will investigate such allegations, hold a hearing or hearings as the Committee determines to be necessary, and shall thereafter report to the Council, furnishing to the Council findings and recommendations of the Committee. Each member appearing at any hearing of the Ethics Committee under this Article shall be entitled to be represented by counsel, who may be a member of the Association or an attorney at law.

6. Any complaint concerning the behavior denounced in Section 3 of this Article shall be referred to the Ethics Committee. Any person, including any member of this Association, may make such a complaint. Each complaint shall be in writing, and shall be signed by the party making the complaint. On receipt of a complaint, the Ethics Committee shall determine whether the complaint is without merit or is frivolous, and if it so determines, the complaint shall be filed without any further action, except to report thereon to the Council. On receipt of such a report from the Ethics Committee, the Council shall have the authority by majority vote to determine whether the complaint shall be laid on the table or whether to order it revived for further study and recommendations by the Ethics Committee.

7. If the Ethics Committee, by majority vote, determines that a complaint against a member warrants further study, or if the Council directs it to make such study, the Ethics Committee shall fully investigate the matter. For this purpose, the resources and the offices of the Association will be made available to the Ethics Committee. If requested by the Chairman of the Ethics Committee, the appropriate District Branch of the Association will assist the Ethics Committee in this investigation. At the conclusion of its investigation and after hearing, the Committee shall make a report to the Council by majority vote, summarizing its findings and recommendations. Any member under investigation is entitled to a thirty-day notice in writing, advising him of the nature of the charges against him, and advising him of the date set by the Ethics Committee of a hearing of the complaint. Any member so charged and notified is entitled to appear before, and to have a hearing by the Ethics

Committee, and to the right of counsel. Any member, if unwilling or unable to travel to the place of hearing, is entitled to submit his answers to the charges in writing. Any member, if unwilling or unable to travel to the place of hearing, on demand in writing addressed to the Ethics Committee, is entitled to appear before one or more examiners designated by the Ethics Committee, who need not be members of the Ethics Committee. Every examiner, however, shall be a Fellow of the Association, who is willing and able to go to the place where the member requests that his hearing be held. Each examiner will report on the facts adduced at such a hearing, together with recommendations thereon to the Ethics Committee. The Ethics Committee is then authorized to take action thereon as indicated in the Constitution and By-Laws.

8. Counsel selected by a member to appear before the Ethics Committee concerning charges against the member will be afforded the right to appear personally before the Ethics Committee; and if he so desires, is entitled to submit briefs on behalf of the member so charged. Such briefs are to be received and considered by the Ethics Committee and by the Council.

9. The Ethics Committee, if it shall determine by a two-thirds vote to recommend that a member be admonished, reprimanded, suspended, or expelled from membership in the Association, shall report its findings and recommendations to the Council for action. The Council shall receive the report, including the findings and recommendations of the Ethics Committee, and the Council shall have authority to admonish, reprimand, suspend, or expel a member from membership in the Association by a two-thirds vote. The Council, if it does not concur in the recommendations of the Ethics Committee for a reprimand, admonition, suspension, or for the expelling of a member, shall, by majority vote, determine whether the matter be closed without disciplinary action. The Council shall notify the member named in the charges of its action. The Council's action will be taken by resolution which shall be recorded in its minutes.

10. The Minutes of the Council's meeting will show the nature of the complaint, the name of the member concerned, the findings and recommendation of the Ethics Committee, and the final action taken by the Council. Unless the member desires it, the name of the member will not be included in the Council's open report read at the Annual Meeting of the Association, nor in the minutes published in the JOURNAL. Any

member having a legitimate interest therein may inspect the Council's full minutes at the office of the Association.

Proposition No. 3

This would remove the requirement that the full text of an election be publicly broadcast.

(3) The last sentence of section 6, Article 6 of the By-Laws is repealed, and in its place the following is inserted:

The full text of the certificate will be filed in the Secretary's office for inspection on request by any Member or Fellow. The net result of the poll, giving only the names of successful candidates, and the text of successfully passed amendment will be announced at the Annual Meeting and published in the JOURNAL.

MUTABILITY

What man that sees the ever-whirling wheel
Of Change, the which all mortal things doth sway,
But that thereby doth find, and plainly feel,
How Mutability in them doth play
Her cruel sports, to many men's decay?

—SPENSER

VALUES

Not all the purple pomp of ancient Kings,
Consuls acclaimed by hosts armipotent,
Caesars upborne on Victory's golden wings,
Augustis girt with war's paludament,
Popes at whose feet the prone world tribute flings,
Are worth one poet's song, one violet's scent.

—JOHN ADDINGTON SYMONDS (1883)

COMMENT

CRIME AND PUNISHMENT

In the field of criminology there are 4 major issues of serious concern; 1. the steady increase in crime, 2. the disproportionate increase in the number of youthful criminals, 3. the question of capital punishment, 4. the criteria by which criminal responsibility may be tested. As a part of this latter issue is the continuing disgrace of the "battle of experts."

The question of the merits or demerits of capital punishment will not be considered here, beyond raising the question whether opposition to this manner of terminating a capital criminal case may not be based somewhat more on sentimental or metaphysical than realistic grounds, perhaps harking back also to an echo of a visionary credo "Reverence for Life."

As a bare matter of record it may be noted that a bill to abolish capital punishment passed by the British House of Commons in 1956 was rejected by the House of Lords by a vote of 238 to 95, the largest ballot in the upper chamber in many years.

The Compromise Bill of 1957 approved by the British Parliament retains the death penalty but restricts it for 5 classes of "capital" murder (1. shooting or causing explosions, 2. killing police officers, 3. killing prison officers, 4. killing during theft, 5. killing while resisting arrest), and to repeated killers. The penalty for "non-capital" murders is life imprisonment. (In connection with the revised status of the murderer in England a newspaper correspondent reports from Cleckheaton under date of July 15, 1957, "more than 50 murders in the 16 weeks since the House of Commons abolished the death sentence for all but a few categories of murder." Only one killer faced the death sentence as his crime happened to fall in category 4 above.)

In 1938 the Labor government in Britain attempted to force through a bill to suspend imposition of the death sentence for a period

of 5 years. The bill was thrown out in the House of Lords by a vote of 181 to 28.

The government of India, where some 9,000 murders are reported annually, has opposed efforts of religious groups, which do not countenance the taking of life in any form under any conditions, to have the death penalty abolished. All the States of India save one—the home of the principal Buddhist shrine—are against abolition. Bills opposing capital punishment have been tabled in both Houses.

In Canada a special committee of the House of Commons and Senate, after a 2-year study, reported to the Parliament in July 1956 favoring retention of the death penalty. The Attorneys General of all but one of the 10 provinces, the exception being Saskatchewan, voiced this opinion.

The question of criminal responsibility has been argued for generations. Of late it has received renewed attention as a result of the test established in the Durham case in the District of Columbia, and which seems deceptively simple and satisfactory. It will probably work though, until some fussy cross-examiner bears down on the definition of "mental illness" which may be about as difficult to define as "insanity"; and we remember what Lord Blackburn said about that.¹ It may not be unfair to ask whether the proponents from time to time, of new rules entertain, possibly, the hope that a perfect rule may be achieved. In any case, considering the material on which a ruling must be made, it is reasonably safe to say that a perfect rule has never been, and is not likely to be, set up. We must do the best we can. Certain approximate criteria were proposed 114 years ago. They have somehow worked. When a procedure works that, according to

¹ "I have read every definition which I could meet with and never was satisfied with any of them, and I have endeavored in vain to make one satisfactory to myself. I verily believe it is not in human power to do it."

William James—or at least the pragmatic side of him—is a pretty fair test of its validity, or at least of its usefulness.

The alarming increase in crime is the stigma of our time, and nothing less than a national disgrace. J. Edgar Hoover, director of the F.B.I. reports (*New York Times*, Apr. 25, 1957) that since 1950 crime has increased almost four times as fast as the population—crime increase, 43%; population increase, 11%. The most disturbing feature of the situation is the mounting numbers of juvenile crimes and criminals. Mr. Hoover states that arrests of juveniles in 1956 increased 17.3% over 1955, whereas arrests in other age groups were only 2.6% higher. This does not mean that there was a disproportionate increase in the number of youthful persons in the population; this increase was only about 3%. More than 40% of the juveniles arrested during 1956 were under 15 years of age, the F.B.I. director reported. "Juvenile delinquency," he states, "is a product of adult neglect . . . a tragic failure of the home, the school, youth organization, and, in fact, the entire adult community. . . . Far too many mothers and fathers today are parents in name only." Whatever causes we may assign, the disconcerting fact is that the combined efforts of all the agencies that have been active over the years in guiding and safeguarding the youthful members of society have failed insofar as stemming the rising tide of juvenile crime is concerned.

In a special editorial in the *FBI Law Enforcement Bulletin*, addressed to all law enforcement officers, and from which we quote with Mr. Hoover's permission, he speaks bluntly and his words require the consideration of the rest of us as well as of the law enforcement officials:

Are we to stand idly by while fierce young hoodlums—too often and too long harbored under the glossy misnomer of juvenile delinquents—roam our streets and desecrate our communities? If we do, America might well witness a resurgence of the

brutal criminality and mobsterism of a past era.

Gang-style ferocity—once the evil domain of hardened adult criminals—now centers chiefly in cliques of teen-age brigands. Their individual and gang exploits rival the savagery of the veteran desperadoes of bygone days. Recent happenings in juvenile crime shatter the illusion that softhearted mollicoddling is the answer to this problem.

Citing a number of instances of atrocious youthful crime, Mr. Hoover continues:

The present appalling youth situations—the crux of our crime problem—demands a vigorous new appraisal. No longer can we tolerate the "tender years" alibi for youthful lawbreaking. This is certainly no time for police to be shackled by illogical restraints based on unreasoned sympathy for these young thugs. Publicizing the names as well as crimes for public scrutiny, release of past records to appropriate law enforcement officials, and fingerprinting for future identification are all necessary procedures in the war on the flagrant violator, regardless of age. Local police and citizens have a right to know the identities of the potential threats to public order within their communities.

The murder of a Maryland school teacher by a 14-year-old student last summer illustrates the danger of unwarranted secrecy. Described as "terrible-tempered" and beyond school disciplining, the boy was expelled from a North Carolina school following a threat to kill his teacher. To avoid corrective action, he was quietly sent off to live and attend school in Maryland. His violent tendencies, kept hidden from both his old and new neighbors, erupted in a classroom tragedy six weeks later when he put a fatal bullet through the heart of one teacher and wounded two others.

Certainly, reasonable leniency for children committing first offences and minor violations is a proper consideration. However, the present major problem is no longer one of bad children but of young criminals. Law enforcement cannot be administered solely according to the yardstick of age. Justice must be meted out to each individual criminal in such measure and manner as the welfare and protection of society demand.

These are strong words, but they are also temperate. May it be that the trends of our boasted humanitarian age toward softness *vis-à-vis* crime in general and youthful crime in particular, and our adherence to the fetish of juvenile irresponsibility, have gone just a little too far?

VETERANS ADMINISTRATION PROGRAM CHANGES

The medical director of the Veterans Administration deserves a special note of commendation for recognizing the need to modify the new two-thirds/one-third rule

with regard to psychiatric residents, *i.e.*, 2 years in a V.A. installation, 1 year in university or other rotations.

We understand that exceptions to this

rule are now recognized as necessary. Such rotations, for instance, that include a block of time in a neurophysiology laboratory, or in a child guidance clinic, are different from the usual hospital service for the sick, either inpatient or outpatient.

Speaking for myself, as well as others who are heading up psychiatric residency training programs, I can say that I have been quite concerned over the new ruling in the V.A. making it mandatory for a resident in the V.A. university training program to spend 2 years in a V.A. installation and only 1 year in university and other training programs. If it is true that there are now some exceptions to this rule, that is, stretching the 1 year, for such block rotations as neurology, child psychiatry, etc., then I think Dr. Middleton has chosen a highly desirable course.

Furthermore, if it is true that a resident may spend more than 1 year in other than V.A. stations by rotating part-time, 1, 2, or 3 afternoons a week while working on a V.A. service, then this fact should be made known to heads of training programs. While I personally believe that nothing less than a block of 6 months full time in a child guidance clinic is of much use to a resident, one could profit by 2 or 3 afternoons a week for a year in an adult psychiatric or neurological outpatient clinic.

I believe that broadening these regulations will do a great deal toward increasing the number of applicants for psychiatric residency training in the V.A.

It is most heartening to read in this year's annual report of the number of research programs that are being carried on in V.A. hospitals, and the number of research positions that are being offered. This in itself is going to do much to enhance the value of the V.A. psychiatric residency training pro-

grams. This will make the 3-year training programs in the V.A. more attractive than ever.

There has been a great hue and cry of late to integrate psychiatric training programs, meaning that there will be no V.A. residents, but only university residents, and the university will rotate the residents where it wishes and for only such periods as it wishes, so long as each hospital pays for the resident while he is there. The same amount of stipend money can naturally buy more residents if they spend only 6 months on a V.A. service—as in some integrated programs; but most fully approved V.A. psychiatric residencies have more to offer a resident than that. This may work for surgical and medical training programs, but certainly not for the average university V.A. psychiatric training program where identification with the service and continuity of treatment are so important for the patients.

This comment is in no way intended to be a criticism of any V.A. training program, rather is it the reverse. I feel that V.A. hospitals and university medical schools have done much to further the training potentialities of each other.

The institutionalized psychiatrist is becoming a thing of the past. Today he must be community conscious. The young psychiatrist on State payrolls now is likely to spend as much time outside of the institution as in, and more and more V.A. hospitals are developing true outpatient clinics for the treatment of patients and their families from the community.

Raising the standards of training and service in our great public institutions, local, state, and federal, is a sure way of doing a better job of treating the mentally ill of America.

NEWS AND NOTES

THE WORLD MEDICAL ASSOCIATION.—The 11th General Assembly of The World Medical Association will convene in Istanbul, Turkey, Sept. 29-Oct. 5, 1957, in the Conference Hall, Faculty of Science, University of Istanbul.

The theme of the assembly, celebrating its first decade of activity, will be: "Solidarity, the Key to Medical Advancement." Program topics will include: 1. The Utilization of the Hospital in Providing Medical Care; 2. Protection for the Civilian Medical Team in Times of Armed Conflict; 3. The Interdependence of the Medical and Pharmaceutical Professions; 4. Medical Editor's Meeting; 5. Scientific Session: "Advancements in Medical Practice in Turkey."

The World Medical Association is the only organization at the international top level that can represent the opinions of the practising doctors of the world. Its current membership includes 53 national medical associations of the free world, representing more than 700,000 doctors. Address of the W.M.A.: 10 Columbus Circle, New York 19, N. Y.

SOUTHERN REGIONAL COUNCIL ON MENTAL HEALTH.—Mr. Paul Harkey, Oklahoma attorney, has been elected chairman of the Southern Regional Council on Mental Health Training and Research. Elected vice-chairman is Dr. M. A. Tarumian, state psychiatrist for Delaware. Three other council members were elected to serve on the executive committee: Dr. Mary Carl, University of Maryland School of Nursing; Dr. Nicholas Hobbs, George Peabody College for Teachers, Nashville, Tenn., and Dr. Cyril J. Ruilmann, Tennessee Commissioner of Mental Health.

The Council was established in 1954 as part of the program of the Southern Regional Education Board. Its purpose is to aid states in training more personnel for mental health programs and increasing research in this branch of medicine. Address of the Council: 881 Peachtree St., N. E., Atlanta 9, Ga.

RUBIN FOUNDATION AWARD TO DR. HOCH.—The first annual Samuel Rubin Foundation Award was made to Dr. Paul H. Hoch, N. Y. State Commissioner of Mental Hygiene, for the most important contributions in the mental health field in 1956. The award was made at the annual dinner of the Postgraduate Center for Psychotherapy, Hotel Delmonico, N. Y., last June, and presented by Mr. Rubin, president of Faberge, Inc.

DR. HUNT HEADS HUDSON RIVER STATE HOSPITAL.—Dr. Paul Hoch, Commissioner of Mental Hygiene, N. Y. State, has announced the appointment of Dr. Robert C. Hunt as director of Hudson River State Hospital. Dr. Hunt is currently director of Erie County Community Mental Health services and associate clinical professor of psychiatry, University of Buffalo School of Medicine. The appointment becomes effective September 1, 1957. Dr. Hunt succeeds the late Dr. O. Arnold Kilpatrick who died in March.

Dr. Hunt has served over 23 years in the department. As assistant commissioner for nearly 5 years, he headed the division of community mental health services since its inauguration in 1954.

THE AMERICAN NEUROLOGICAL ASSOCIATION.—At the 82nd annual meeting of The American Neurological Association held in Atlantic City, N. J., June 17-19, 1957, the following officers were elected for the coming year: president: Israel S. Wechsler; president-elect: Bernard J. Alpers; 1st vice-president: Russell N. DeJong; 2nd vice-president: Bronson S. Ray; secretary-treasurer: Charles Rupp; assistant secretary: William F. Caveness.

The 83rd annual meeting of the Association will be held at the Claridge Hotel, Atlantic City, June 16-18, 1958.

S.K.F. FOUNDATION FELLOWSHIPS.—The American Psychiatric Association has announced the award of 19 Smith, Kline &

French Foundation Fellowships in psychiatry. Thirteen of these enabled medical students to participate in psychiatric research or training programs in the summer, and 2 other students programs are just starting. In all, 34 undergraduates from New York State to Washington will participate in projects ranging from a study of the chemical functionings of the brain to an analysis of suicide rates.

The Smith, Kline & French Foundation is the independent philanthropic arm of Smith, Kline & French Laboratories, Philadelphia. The Foundation has given The American Psychiatric Association a total grant of \$90,000 for the 3 years 1955 through 1957. The fellowships established through this grant are administered by a committee named by The American Psychiatric Association.

AWARD TO DR. SILVERMAN.—Dr. Baruch Silverman, director of the Montreal Mental Hygiene Institute recently received a citation and a \$1,000 award for his contribution to mental health in Canada. The award was presented at the annual meeting of the Institute. Dr. Margaret Mead, president of the World Mental Health Federation was the guest speaker at this meeting.

POSTGRADUATE COURSE IN PSYCHOSOMATIC MEDICINE.—The department of psychiatry of the Temple University Medical Center is inaugurating a postgraduate course in psychosomatic medicine beginning October 2, 1957. The course will include supervised clinical experience as well as lectures and demonstrations, and will run for 20 Wednesday sessions, supported by a grant from the Smith, Kline & French Foundation of \$3,580. It is open to general practitioners, medical or surgical specialists, State hospital psychiatrists, as well as psychosomatic specialists.

H. Keith Fischer, M.D., will direct the course presented by a group of faculty members headed by Edward Weiss, M.D., and O. Spurgeon English, M.D.

PSYCHIATRIC RESEARCH REPORTS No. 7.—The Washington office of the A.P.A. has recently issued the 7th in its series of re-

search reports. The 7th report contains the papers delivered at the A.P.A. regional research conference at McGill University Nov. 18-19, 1955 and is titled, "Stress; Experimental Psychology; Child Psychiatry," and edited under the chairmanship of Jacques S. Gottlieb and consultant editor Robert A. Cleghorn. Orders should be addressed to: Psychiatric Research Reports, American Psychiatric Association, 1785 Massachusetts Avenue, N. W., Washington 6, D. C.

ACADEMY OF PSYCHOSOMATIC MEDICINE.—The program of the 4th annual meeting of The Academy of Psychosomatic Medicine to be held October 17-19, 1957, at the Morrison Hotel, Chicago, will be devoted to "Psychosomatic Aspects of Obstetrics, Gynecology, Endocrinology and Diseases of Metabolism." The meeting will be open to all scientific disciplines, as well as psychologists, social workers and nurses. Information may be obtained from Dr. William S. Kroger, Secretary, 104 South Michigan Avenue, Chicago 3, Ill.

EASTERN PSYCHIATRIC RESEARCH ASSOCIATION.—The program of the second annual meeting of the Association is as follows:

Friday, October 11, 1957, at Kings Park State Hospital: Symposium on succinylcholine technics with clinical demonstrations; Symposium on electro-sleep technics with clinical demonstrations.

Saturday, October 12, 1957 at the Waldorf Astoria Hotel, N.Y.C.: Round Table Discussions on the following topics: The function of the anesthetist in electroshock-therapy; the newer psychiatric drugs; experimental investigations; the usefulness of non-convulsive technics, etc.

Symposium on progress in genetic psychiatry.

Award of the R. Thornton Wilson \$1000.00 Prize on genetic or preventive psychiatry to the author of the presentation adjudged best in the Symposium on progress in genetic psychiatry.

There will be a registration and luncheon fee for the Waldorf Astoria Hotel Meeting; but no registration, luncheon or other fee for the Kings Park State Hospital Meeting.

The Meetings are open to all members of the medical profession.

BOOK REVIEWS

CRIME, COURTS AND PROBATION. By Charles Lionel Chute and Marjorie Bell. (Toronto: The Macmillan Co., 1956. \$4.75.)

Charles L. Chute was executive director of the National Probation and Parole Association for many years. He began this book shortly after his retirement but died before he could finish it. Miss Marjorie Bell, assistant director of the National Probation and Parole Association and the editor of its magazine, *Focus*, completed it. Anyone who has worked on another's unfinished manuscript knows the difficulties she faced. Miss Bell, however, has done an admirable job. The book contains an excellent introduction by Roscoe Pound whose interest in probation is well known.

The book is an accurate and gripping history of probation and its development. But it is much more than this. Chute's and Bell's own views are expressed, sometimes vehemently. The book's opening sentence is typical and startling. It might even alarm the uninitiated. It reads: "Threading through the history of civilization, the trail of pursuit and punishment of the law-breaker, is almost as bloody as the trail of crimes committed."

The first chapter vividly recites the ferocious punishments applied, until recently, under the Anglo-American systems of criminal sanctions. In this connection Chute and Bell note that flogging, both of adults and children, under court order in England was not finally abolished until 1948, and that the whipping post is still legal in Delaware and Maryland. The authors point out the often repeated truism that severity defeats its own purpose.

Succeeding chapters deal with the development of probation in England and in the United States. Early plans for the humanizing of criminal penalties arose first in England. Systems of recognizance and transportation were created. The authors point out that individual social treatment of criminals was first employed in the cases of children and youthful first offenders and that early in the nineteenth century English magistrates themselves experimented with a rudimentary probation system to avoid sending young and inexperienced offenders to prison. *Wile*, Matthew Davenport Hill, the famous Recorder of Birmingham, who in 1841 employed parents and masters of apprentices as probation officers. It was not until 1907 that Massachusetts organized the first official probation service in the United States. The Massachusetts system was studied by Parliament and served as the basis for a bill introduced into the House of Commons in 1907.

Crime, Courts and Probation lays emphasis on the very able work done by John Augustus, the pioneer in probation work in this country. This remarkable man first took under his care only men charged with drunkenness. Later he supervised both men and women charged with other offenses.

Augustus' work was entirely voluntary and carried on at his own expense.

A very considerable portion of the book is devoted to the work of Chute and others in securing the enactment of the Federal Probation Act. Anyone who has worked with Congress will find these chapters intensely interesting. They demonstrate Chute's tenacity when he desired to put a fine idea into effect. It is interesting to note that even as late as 1919 there were judges who felt that probation would detract from the efficiency and majesty of the law. But many lawyers and judges were of the contrary view and, I am glad to say, did not hesitate to lend their support to the enactment of the legislation.

This book is an impressive one. It gives the only complete review of the creation of the probation systems that the writer has encountered. The work is a mine of information, accurately presented. It should be in the library of every person who is interested in the Anglo-American system of punishment. The authors have performed a not inconsiderable public service.

JUDGE JOHN BIGGS, JR.,
U. S. Court of Appeals,
Philadelphia, Pa.

MENTAL HEALTH AND HUMAN RELATIONS IN INDUSTRY. Edited by T. M. Ling. (New York: Paul B. Hoeber, Inc., 1955. \$6.00.)

This book is not only intensely interesting and stimulating but it is also delightful reading, and should be read by everyone who comes in contact with management in industry and in the relationships between people in all categories. Certainly all psychiatrists, industrial physicians and personnel officers should be thoroughly familiar with its contents.

Dr. T. A. C. Rennie's introduction succinctly states the meaning of it all: "There can be high industrial morale with contentment and happiness for both employees and managers and industrial stability only when men feel strongly that what they are doing is worthwhile and worthy of them, when all have a real sense of participation in the total task, when there is mutual acceptance of one another's contribution to the whole enterprise, and when there is congenial and democratic give-and-take in all working relationships."

Lord Horder points out that in accepting modern conditions of work, an individual may submerge himself for the good of the unit and in support of the total effort. He maintains his individuality through his interest in the total scheme of things and his participation in the affairs of the community.

T. M. Ling, in beautiful simplicity, explains the goal of man's struggle—"The business of life is always to seek the highest and to do the best possible."

sible in any situation." He shows that it is the function of a mental health program in industry to insure the maximum of collective achievement with the minimum of individual stress.

Ling also covers causation of accident, illness and the emotional factors involved, and the responsibility of management in convalescence and rehabilitation. He indicates that "the program extends beyond medical care to social-economic problems calling for combined action by the doctor, the personnel manager, the industrial psychologist and others."

V. W. Wilson thoroughly discusses the need for careful selection, thorough training, recognition of emotional needs, and the usefulness to every man of social relationships on and off the job. He also includes matters pertaining to the significance of positions, promotions and transfers as related to mental health. The need for harmony in top groups to engender harmony in sub-groups is apparent, and ways of bringing this about are explained. He has stressed "the need for careful consideration of the individual and the group in achieving efficiency in an industrial organization."

In discussing environmental factors influencing health, H. G. Maule writes of factory and plant layout and the importance of adapting machine to the functional requirements of man in an effort to lessen stress. He also suggests the need for work arrangements in such a way that there may be job completion not only as a production aid but to establish contentment and a sense of satisfaction and accomplishment on the part of the worker.

The responsibility of management for the health of employees is discussed by Dr. J. J. O'Dwyer, who also stresses the necessity for specially trained medical staff, who may then have the ability to work well with management and with the worker. He places the responsibility for the establishing of a healthy mental climate upon the cooperation of a health team with administrators and technical experts.

In outlining the obligations and contributions of the personnel managers, H. Watton Clark has clearly shown that the successful discharge of the personnel manager's responsibility in relation to mental health rests to a large extent on the effectiveness of communication between his department and the other departments of the company. The keynote is full information and full cooperation all along the line.

Signs of aggression and methods of handling these emotional strains are discussed by R. F. Tredgold who suggests substitute channels of release such as sports, etc., but more fundamentally indicates the need for thoughtful planning to avoid situations and conditions which will bring about animosity and arouse antagonism. He also portrays the place of the psychiatrist in industry and outlines some of the problems the psychiatrist may meet and some of those he may inadvertently create. The need for collaboration between the industrialist and the psychiatrist is most essential. It is important that the psychiatrist indicate clearly what he has to offer and in a decidedly practical manner. "He must understand the background of industrial behavior, the language and conversation of in-

dustry. . . . He must be able to listen and to discuss policies with top management and he must be able to walk through the factory and talk easily with the workers at the bench. . . . He must learn that he may teach. . . . He must handle groups as well as individuals."

Cases are frequently referred to the industrial psychiatrist by other industrial physicians, but it is up to the psychiatrist to recognize the patient in his work-setting and in his social environment.

The psychiatrist can contribute in research, in treatment, in education, and in selection. The essential factor is the building up of understanding between industry and psychiatry.

"The object of research in industrial management is not always to make it possible to alter the situation, though this must be dealt with, but rather to alter one's method of adaptability most effectively to the situation as it is." With this observation, Dr. James F. Scott broadens the concept of research in industry and indicates that those in this field should have a clear understanding of management and a clear understanding of the worker, for this is a highly specialized field and requires a full appreciation of the practice of industrial management.

The interplay between society and work is interestingly presented by Dr. T. A. Lloyd Davies, who positively states that work is a social habit. With this concept many reasons why a man works are outlined and discussed. That the selection of certain jobs is often based upon social reasons, such as because friends are there, demonstrates the need for conformity and for group association which leads to group interests and eventually establishes job standards.

A. M. Smith has indicated that a job must have meaning, and must be worth doing, and that when the work is right, the worker will be healthy.

In summation, T. A. Ling points out that teaching of human relations in industry should start from the top and work down; that the teaching should be dynamic with wide use of group discussions. He presents an interesting review of studies now going on in reference to human relations in industry throughout the world.

N. C. Rimmer reviews the implications of this book for management. He clearly understands the pertinent, significant and practical values that are available here. In discussing leadership, he indicates that a successful manager must like, understand and accept responsibility for people; develop a scientific attitude toward his worker; he must be articulate and develop skill in expression appropriate to the occasion. He must also feel personally the issues involved. He observes that the teaching of mental health in human relations demands the practice of good mental health in human relations and in the training situation.

Management is invited by this book to look at the "whole man" and to examine the "total situation." It appeals for greater understanding of basic human needs and of what exists below the surface in interpersonal relationships.

ALAN GREGG, M. D

IN MEMORIAM

ALAN GREGG, M. D., 1890-1957

Alan Gregg was the friend of countries and institutions and medical scientists around the globe wherever the advancement of the healing art might serve the needs of mankind. During 20 years as director of the medical sciences of the Rockefeller Foundation he was able by wise counsel and the awarding of substantial grants to promote medical teaching and research in many lands.

Only last year he left his New York office in the heights of Rockefeller Center, and his post as vice-president of the Foundation and retired to his house in the mountains of California.

Retirement cannot be said to have ended his professional career, for the work he initiated does not stop and the lines of advance he charted will continue.

A native of Colorado Springs, Dr. Gregg received his medical degree from Harvard and after his intern year and another year with the Harvard Medical Unit attached to the British Army in World War I, he joined the International Health Board of the Rockefeller Foundation (1919), with which organization he was to devote his professional life.

If ever a man seemed chosen for a specific job by the arbiters of fortune, Dr. Gregg was the man and this was his job. As director of the medical sciences of the Foundation he had power and the wisdom to use that power, and world medicine is the better for that collaboration and support. As the New York Times comments editorially, "Alan Gregg has laid down patterns that medical men are likely to follow for a long time."

In his wide view as medical statesman he gave thought to the immediate task that lies before the medical and allied sciences, "to make use of the immense store of knowledge accumulated in the past eight decades and particularly in the past two or three" to insure the better health of all the people. He noted the difficulties attendant upon the

rising costs of medical and hospital services of all kinds and expressed a preference for voluntary prepayment plans rather than those state ordered and directed.

Dr. Gregg's purview included the broad field of public health, but in some areas he had a special interest. One of these was psychiatry. "I am most interested in the human side of medicine," he said. From the first he realized that developments in this segment of medical science was not on a par with those in other segments and that one of the reasons was its lack of integration into the whole body of medicine. He lent his help to the correction of these faults, and when on retirement he looked back over the years, he could feel that his efforts had indeed contributed materially to the better state of affairs that exists today.

When the centenary of The American Psychiatric Association, of which Dr. Gregg was an Honorary Fellow, was to be celebrated at the annual meeting in 1944, it was recalled that 50 years earlier Weir Mitchell had been invited as a non-member of the Association to criticize the psychiatry of that day—*asylum psychiatry*. Accordingly it was felt that at the 100th anniversary a qualified critic should again be sought. The choice naturally fell upon Alan Gregg. He accepted the challenge. He spoke as openly as Weir Mitchell had done; and he spoke to a receptive audience. Much of the betterments he then urged have been realized.

One of his latest contributions—and this within the past year—was his sponsorship and vigorous support of the Bill which was passed in Congress establishing the National Library of Medicine in a new building to be erected in Washington, thus ensuring suitable housing for this great library, formerly the Library of the Surgeon-General, and provided for its proper operation and expansion.

In November 1956 Dr. Gregg received a

special Lasker Award from the American Public Health Association, honoring him as "exemplar *par excellence* of the well-being of mankind throughout the world, public health statesman, influential medical educator, wise counsellor and friend."

And at its recent Convocation (1957)

Western Reserve University conferred upon Dr. Gregg the degree of Doctor of Science with the citation: "a wise counsellor with purity of motive, he encouraged and stimulated those who turned to him for wisdom, detachment and broadened perspective."

C. B. F.

KNOWLEDGE AND WISDOM

Knowledge and wisdom, far from being one,
Have ofttimes no connection. Knowledge dwells
In heads replete with thoughts of other men;
Wisdom in minds attentive to their own.
Knowledge, a rude unprofitable mass,
The mere materials with which wisdom guilds,
Till smooth'd and squared, and fitter to its place,
Does but encumber whom it seems to enrich.
Knowledge is proud that he has learned so much;
Wisdom is humble that he knows no more.

—WILLIAM COWPER

FELLOWSHIP LECTURE

EUGEN BLEULER AND PRESENT-DAY PSYCHIATRY¹GREGORY ZILBOORG, M.D.²

Observing anniversaries of births or deaths serves not only the conscious purpose of attesting our respect for those whom we value and love. It also serves the purpose of establishing the continuity between us and those who are no longer with us, and of asserting a kind of almost personal claim on the contributions which never were ours but of which we would like to consider ourselves legitimate heirs and therefore legitimate possessors. This claim is not always justified, but such is the way of men. We are apt to cling together more by solemnizing our past than by cultivating true ties with the present.

This circumstance makes the task of the historian not very grateful and a little uncertain. As a contemporary he cannot help but find himself one of the chorus singing praises, yet as a historian he must step back as it were, knit his brows or half close his eyes in order to see a little further, to establish a perspective, and to reconstruct a relationship between events and men which would to some extent at least reveal the inner dynamics of the course of events which we call history. While it is almost always true that history repeats itself, it is important that the historian not become a repetitious valedictorian of the reconstructed past.

The historian therefore cannot, at any rate he ought not to, overlook certain manifestations of history which may not be entirely consonant with the traditional tone of praise. After all, anniversaries and particularly centenaries of birth are not an appeal for funeral orations; they are stern even though solemn calls for appraisal of our own historical vision, which if expressed with charity for all must however not overlook the sunspots no matter how blinding the light of the sun itself.

It is because of these considerations that one must recall that in 1956, when the celebration of the centenary of Freud's birth took place, The American Psychiatric Association, cooperating in full measure with the American Psychoanalytic Association, represented a rather singular picture of Freudian exclusiveness so to speak. The centenary of Freud was duly observed as it should have been. Here and there stray objections were heard to many things Freud partly did and mostly did not say, but the celebration was dynamic and almost overwhelming. The name of Emil Kraepelin was hardly, if at all, mentioned—as if Kraepelin belonged to another era, long dead and buried. Yet, only a few months before, the hundredth anniversary of the birth of Kraepelin had been celebrated in Munich. Kraepelin was only three months older than Freud, which hardly makes him a man of a generation before Freud. Yet the apparent relegation of Kraepelin to an older generation and of Freud to a newer one has become a sort of tradition in psychiatry, particularly in American psychiatry. One wonders why. Kraepelin became professor of psychiatry at the University of Dorpat (in 1886) in the same year that Freud entered private practice. Yet while more advanced in his academic position, Kraepelin's true and original productivity began in 1896 when he formulated his concept of *Dementia Praecox*, whereas Freud's first contribution to psychopathology, "On the Psychological Mechanisms of Hysteria (preliminary communication)," appeared three years before, which would make Freud a sort of scientific elder of Kraepelin. Freud could also be considered the scientific elder of Eugen Bleuler, who was eleven months younger and whose *magnum opus* did not appear till 1911—the second volume of Aschaffenburg's *Handbuch* entitled "Dementia Praecox—*Die Gruppe der Schizophrenien*."

It is obvious that the three great men

¹ Delivered at the 113th annual meeting of The American Psychiatric Association, Chicago, Ill., May 13-17, 1957.

² Address: 33 East 70th St., New York 21, N. Y.

whose names come to everyone's mind whenever modern psychiatry is being discussed were actually contemporaries, and it requires some historical and psychological analysis in order to understand why one of them is considered "old" and another "new," and why the one in the middle (I have in mind Bleuler), while known all over the world for having introduced the new term "schizophrenia," remains a comparatively obscure figure, as does also his actual concept of **schizophrenia**. As a matter of fact the United States, so quick to respond to and to utilize anything new, waited over thirty years before Bleuler's volume on the schizophrenias was translated into English. Yet Bleuler was a sufficiently well established psychiatric personage to be one of those who upon the invitation of Adolf Meyer came to America to participate in the exercises opening the Phipps Clinic in Baltimore. It was there that he offered American psychiatrists his paper on Autistic Thinking.

It would be rather a platitudinous thing to say that Freud's revolution in the field of psychopathology was the greatest known to us since the sixteenth century. It would be rather superficial to observe that Freud's greatness was responsible for the crowding out of our otherwise rather fresh memories of Kraepelin and Bleuler. Revolutionary and great as Freud unquestionably was, it is somewhat puzzling to observe that Freud, who disliked America so thoroughly and so openly, seemingly eclipsed Kraepelin who was known to many in the United States personally and sympathetically, and at least overshadowed Bleuler who was known to many Americans and who sent his son, now his successor to the chair of psychiatry in Zürich, to an American mental hospital for postgraduate studies. Moreover, Freud's own contributions to clinical psychiatry were secondary if not indirect or minor. For many years Freud admonished his followers to be satisfied with the treatment of neuroses and to keep away from psychoses. Clinical psychiatry was not Freud's forte.

It would seem therefore that the overemphasis on Freud, to the point of apparently neglecting the memories of Kraepelin and Bleuler, must have been due to circumstances not directly connected with clinical psychi-

atry itself. Apparently the cataclysmic changes brought upon the world by Russia and the subsequent World War II were in no small degree responsible for the paradoxical turn of some of the external trends of American psychiatry. The great centers of psychoanalytic, Freudian teaching in Berlin, Vienna and Budapest were annihilated; the British Freudian center, despite the physical presence of both Freud himself for a while and Anna Freud, was temporarily stunted by the blitz over London. A displacement of psychoanalytic forces occurred like an elemental rolling of intellectual and scientific waves. Many if not the majority of Freud's co-workers old and young reached the shores of the United States, and as a result America became the largest and strongest center of Freudian psychoanalysis.

To deny that this resulted in a great contribution to American psychopathology would be foolish and ungrateful, but to overlook some of the negative aspects would be just as foolish. Already in the early twenties Eugen Bleuler was moved to state that unlike the earlier work of psychoanalysts the later psychoanalytic writings were based more on theory than on clinical observations. This particular aspect of psychoanalysis became more pronounced than was good for clinical psychiatry. At the turn of the century August Hoch, the successor of Adolf Meyer in the New York Psychiatric Institute, John T. McCurdy and others sought to utilize psychoanalysis in the service of clinical psychiatry. It is to be noted that not only were these beginnings of American psychoanalytic psychiatry not mentioned in the course of the Freud centenary celebration but, were it not for the solitary voice of Karl Menninger, the name of Brill, to whose efforts we owe the formation of the section of psychoanalysis in The American Psychiatric Association, would not have been even mentioned, as would not the name of William A. White, the president of The American Psychiatric Association who was the first to put the name of Freud in a presidential address.

Perhaps it is just as well that the centenary of Freud's birth was so celebrated, since it thus helped to remind us of those whom we had forgotten in that singular

into the ideational and affective content of his patients. "In the place of neuroanatomy came the actual *meeting* of the patient's personality, and instead of the microscope (the chief instrument) came human speech."⁶ This is as far as I know the first approach in clinical psychiatry which one may rightly call by the modern term "existentialist."

It is ever more and more fascinating to discover how history always finds its man. The Hippocratic tradition in psychiatry is unthinkable without its being followed by the school teacher, by the methodical professor, by the bookman and laboratory compiler—a Kraepelin. It is impossible to imagine the discovery and the unmasking of the unconscious without imagining a restless, almost solitary mind plumbing the depths instead of mapping out the great open spaces, a mind both bold and secluded, perseverant rather than elastic, a single-minded mind whose concern is more his own idea than the mystery that is man. Freud—the anxious intellectual, the intolerant libertarian—was this kind of mind.

It is difficult to imagine an existential approach to man in sickness and in health without imagining a simple man who cares more about what you say and feel than what you might be or what your liver would look like under an oil immersion lens; a man who likes people and who likes to live with people; who wants to speak and hear the language of simple folk and watch them and observe them plainly, simply, without flight into a fantasy of improvised imagery and without reading into a fellow human being that which he is not. It requires a modesty of spirit and humility before that which is living. Eugen Bleuler was this kind of man and this kind of mind. Academic distinctions, which came so easily to Kraepelin and to which Freud so fervently and anxiously aspired, meant rather little to Bleuler. He lived with and for his patients, some 850 of them while he was in Rheinau; these patients as well as the attendants called him Father—although he was only 29 when he joined them as the head of the hospital, and only 41 when he was called to Burghölzli to succeed August Forel and become professor of psychiatry in the University of

Zürich. He responded to this call primarily because he wanted to be closer to his parents who began to show signs of aging, closer to the place where he was born, the village of Zollikon in the canton of Zürich. There he came to work and to teach, there he stayed after he was pensioned, and there he died in 1939 at the age of 83.

Bleuler was a close friend of Kraepelin, and he was in correspondence with Freud till two years before their respective deaths. It is not that Bleuler occupied some "middle ground" position between Kraepelin and Freud—his was rather a simple, human position. Freud once remarked with characteristic asperity that Bleuler introduced the term "ambivalence" as if implying that it was Bleuler's own ambivalence toward psychoanalysis that led him to the creation of the term. It would perhaps be more correct to say that Bleuler thus anticipated Freud's discoveries of the various polarities in the psychological structure of man.

Bleuler was as direct and matter-of-fact as the simple people of his native village, and he neither minced words nor engaged in polemical rhetoric. One of the many examples: "A critic," writes Bleuler, "says that in the beginning I was formally devoted to the old theories of Freud, but that then I dropped some of them. He is mistaken."

It would be rather a lengthy task and, since the English text of "The Group of Schizophrenias" has now been published, it would be rather repetitious to try to recapitulate Bleuler's views on schizophrenia. Even though he is best known for his description of schizophrenia, Bleuler's place in the history of psychiatry is due pre-eminently to his fundamental, existentialist orientation which is also reflected in his formulation of schizophrenia. The term "existentialist" as used here ought to be understood in its direct and simple meaning. It has little to do with the existentialist philosophy of Jean Paul Sartre, which is essentially nihilistic, or that of Heidegger, which is more confusing than profound but essentially non-psychological, or the too abstract, even though more psychological, ex-

⁶ *Idem.*

⁶ Das Autistisch-Undisziplinierte Denken in der Medizin und Seine Überwindung. 4th ed. Berlin 1927.

ism of Karl Jaspers. Bleuler's approach was strictly observational and he avoided being involved in any philosophizing. He looked for the solution of the riddle of that which is psychological and he seems to have been inclined more toward a positivistic point of view, yet without losing contact with the actual human being. It is worthwhile recording that the psychological, the psychic, "the psychoid" as he called it, intrigued him to the very last moment. On his death-bed he was busy putting together various notes he had made for the preparation of a book to be entitled "The Soul of Plants." He lay there slowly writing till the pencil dropped out of his weakened hand as he passed away.

One is justified in saying that he was a lifelong seeker after the truth, particularly the truth about man. He was not a fanatic of any special theory, or a devotee of some favorite set of concepts, nor was he an eclectic. In his quiet way he took life and people and events as they came. This does not mean of course that he was a cold, dispassionate empiricist. He was a teetotaler, for an instance, and a passionate one. His heart would not rest as long as Switzerland showed the highest rate of alcoholism in Europe, if not in the world. Directly connected with his fervent loyalty to human beings was his devotion to the Swiss dialect. At first one might mistake this for a kind of exaggerated patriotism, but it was not this. In order to live and understand people you must speak their language, not in this case the language of the cultivated, intellectual, "high" German but the simple dialect of the peasant, the little man of his canton of Zürich.

It was this simplicity and directness of the little man, whether worker or peasant, that Bleuler loved. Bleuler himself was of this simplicity and lived by it. This is apparently one of the reasons why he was so opposed to that thinking in medicine and psychiatry which he called "autistic thinking"—a form of thinking more related to spontaneous, wish-fulfilment ideation than rational, realistic thinking. In 1919 Bleuler devoted a book to this subject, and he entitled it "The Autistic-Undisciplined Thinking in Medicine." It went through four edi-

tions, the last one appearing in 1927. The book is a keen and sharp indictment of the medical profession for its wish-fulfilment, unscientific thinking, a type of thinking which perverts the very art of healing and the very spirit of medicine. Bleuler shows here that he is a master of direct language which is both clear and bold. Thus in discussing the question of degeneration, which was introduced by the French psychiatrist Morel, Bleuler says:

When we read: the patient on the mother's side comes from a very old family, on the father's side from a younger one—well, I understand quite well what the writer wants to say about the characteristics of the old aristocratic family and the upcoming family of the father's side, but the whole conception is false.⁷

With similar directness he speaks in a footnote added in 1927.

It would be quite timely finally to stop the battle as to whether schizophrenia is a disease entity or a "real" disease. If the idea is really not clear yet, then one might at most discuss to what extent and in which sense the concept [of schizophrenia] unites certain things that belong together, and then one could consider whether this type of unity serves the purpose of our conception or whether it is useful. The concept "fish" designates a unity; that of "mammal" does the same. The concept "whale" is also a unit, but of a different order. There was a time when the whale was considered to be a fish. If now we were to consider animals from the standpoint of their method of locomotion, the whale would become a fish all over again.⁸

This is the language of a man who does not set high store in purely conceptual thinking. To Bleuler, concept apparently must be an expression and serve the needs of reality.

This word "reality" may be easily misunderstood here. During the last thirty years it has been used both as a philosophical and a psychological term, and at times to the detriment of clarity both in philosophy and psychology. Unfortunately, the word "reality" has no synonym in the English language. It has been in use for over four hundred years, and we do not possess in our language a single word that would be the proper equivalent of the German term which Bleuler used, namely: *Wirklichkeit*, which means not so much "reality" in the broad sense of the term as "real existence." It is

⁷ *Ibid.*, f.n. p. 61.

⁸ *Ibid.*, f.n. pp. 59-60.

the relation of the individual to his own existence and to the existence of other people and things that in the view of Bleuler mattered in the life of man.

That is why Bleuler's vision was focused not on the mental illness called *Dementia Praecox*, an illness which was supposed to have its own course and its own outcome, as if it were something having its own existence within a given individual who happened to be the victim of it or affected by it. Bleuler was primarily interested in the manner in which the schizophrenic *lived* his own life in relation to what is designated as *Wirklichkeit*.

It was therefore important to Bleuler to bring together all those psychopathological manifestations which showed a certain discrepancy between the various functions of the personality, a certain discrepancy between the affect and the content of thought, a certain discrepancy between the word and the deed, a certain discrepancy between thought and actuality. It is these discrepancies that led Bleuler to invent the term "schizophrenia," the splitting of those psychological functions of man which are usually integrated into one whole. Hence, Bleuler's concepts of ambivalence, affectivity, autistic thinking, dereistic thinking and syntony which gained general recognition and usage. Hence, too, Bleuler's assertion as early as 1907 (although it was not published until 1911) that

if a given patient wants to stand on his head, or to break windows, or to tear his clothes, etc.—all this is not a result of the process of illness (*Krankheitsprozess*) but a reaction (I mean a psychological reaction) to inner and outer experiences (psychological).⁹

It is remarkable to what extent Bleuler remained inwardly true to his respect for the unitary quality, for the indivisibility of the human person. In this respect he stands in intimate relationship to Freud, whose greatest contribution to the knowledge of man was just this; from the scientific, and not only from the philosophical and spiritual, point of view, man is one in health and in illness even when he manifests himself to us as "split," as schizophrenic.

It is impossible to say whether the priority

in this respect belongs to Freud or Bleuler; it is most probable that both were moving in the same direction, and it would seem that both were drawn toward one another by the discovery of the richness and awesome power of the unconscious. Despite external appearances to the contrary, I am inclined to believe that Freud had more Bleuler in mind than his assistant Carl Jung, when he said that most of his followers and collaborators came to him via Zürich. Abraham, Brill, Jones and many others were exposed for various lengths of time to the influence of Eugen Bleuler in Burghölzli. Bleuler was one of the first contributors and coeditors of the *Jahrbuch für Psychoanalytische und Psychopathologische Forschungen*.

To Bleuler, schizophrenia was a complex gathering of psychological reactions. Here we come upon one of the most striking paradoxes in psychiatric clinical thinking. He stated without ambiguity that "At present, the only therapy of schizophrenia to be taken seriously is the psychological therapy."¹⁰

Yet Bleuler believed that after all is said and done schizophrenia was an organic disease. Freud, as is known, in a similar way stressed the psychological aspects of mental illness, but hoped that some day some physico-chemical agents responsible for the illness would be found. On the other hand Adolf Meyer, more strictly of the biological bent of mind, thought schizophrenia to be of psychological origin. This point was one of the most important in the scientific dissension between Eugen Bleuler and Adolf Meyer. However, Bleuler gravitated toward the psychological without separating it from the organic. He even wrote a little book on "The Psychoid as the Principle of Organic Development." It was published (in German) in 1925.

Bleuler seemed to be closer to vitalism and to Lamarck than he himself appeared to know. As a result he is one of those who, like Freud, was inclined to avoid drawing a clear line of demarcation between the normal and the pathological in the psychological functioning of man. He was more interested in what the given person did than with what kind of illness he was possessed of. That is why he was opposed to the idea

⁹ M. Bleuler. *Op. cit.*, p. 113.

¹⁰ *Idem*.

that a mere diagnosis of schizophrenia is sufficient to relieve one of criminal responsibility. He specifically stated that it is the lack of freedom of the will in a given case, and not the diagnosis of a given "disease," that should be considered the main factor whenever the problem of responsibility arises.²¹ Traditional as this point of view might appear at first, Bleuler was in actuality rather consistent. He would not bow to mere labels, even diagnostic ones; he bowed only to human facts.

Another outcome of this abolition of the strict line of demarcation between the mentally healthy and the mentally sick was the utilization of various psychological reactions in the analysis of our social life. In this respect Bleuler, like Freud, saw the same psychological mechanisms operating in our normal social life as in the pathological life of an individual. However, there was this difference between Freud and Bleuler. Freud, as is known, equated the social organism with that of the individual, and he saw the same pathology in society as in a person. Bleuler on the other hand avoided this methodological error; he did not consider the given psychological mechanism pathological in itself, but only the ethico-sociological consequences of certain psychological trends. In other words, Bleuler remained consistently opposed to reliance on diagnostic labels, not only in clinical or forensic psychiatry but also in social psychology.

This, I believe, is one of Bleuler's greatest merits, and one of his most valuable contributions. Thus he was able to rise to great heights of moral and scientific evaluation of human behavior. As a physician he knew the sick man as few psychiatrists of his day, and perhaps of ours, did. He took his post in Rheinau—a lonely spot on the Rhine in a place that as late as 1867 was still a Benedictine monastery removed from the worldly world. There the young Bleuler started being a psychiatrist. At that time this meant that he actually had to lay aside, for most of the time, the microscope and the neuroanatomic preparations which he had learned to use so well at Gudden's laboratory in Munich, because he had to become

caretaker, housekeeper, surgeon, dermatologist, internist and most of all the gentle friend of 850 patients. Epidemics would flare up; then to his many roles and preoccupations would be added those of a public health officer. This is how one learned psychiatry in those days. The manner and the method of such learning, the hard and yet the fullest way, is reminiscent of those which were imposed by necessity upon the physicians of the institutions and retreats in the days of Philippe Pinel, and some half-century later upon the founders of The American Psychiatric Association.

Young Bleuler, not yet thirty, quickly started taking into account the failures, errors and weaknesses of his day. He jotted down his many experiences and heartaches so that some thirty years later, already a mature and seasoned psychiatrist and a professor at the University of Zürich who had seen the world (he had at that time already visited America for the first time), he wrote what might be called his brief against the medical world of his day. *Das Autistisch-Undisziplinierte Denken in der Medizin und Seine Überwindung*.

In quality of thought and intensity of feeling, this book surpasses many of his other works, not excluding perhaps his "Group of Schizophrenias." It was a straightforward restatement of what he meant by autistic thinking in our daily, non-psychotic life, and a severe indictment of our professional propensities. He did not overlook the positive aspects of medicine, but, as he said in the preface to the first edition of the book in 1919, "Here it is necessary to bring out the mistakes [of medicine]. With all that is good in medicine, this work cannot busy itself." One at once notes the tone of a pamphleteer, yet a special type of pamphleteer, an objective, impersonal one. He attacks no one by name or place; he is aggressive without being bitter and sharp, without being angry and devastating, without being really harsh. Many of the examples given in this book, many an aspect of medicine of some four decades ago, would appear to us already superannuated; science and medicine have moved fast since 1919. Yet the substance of the book is still as fresh and alive today as it was when it first

²¹ E. Bleuler. *Das Autistisch etc.* 4th ed., p. 56 f.n.

appeared, perhaps even more alive because we know now so much more and therefore ought to know and do better.

Bleuler points out to what extent the medical profession is given to autistic thinking in its medical practice as well as in its theoretical elaborations. It is accustomed to that type of thinking which pays no attention to the dividing lines between human experiences and the verification of these experiences by looking at the actualities (*die Wirklichkeit*), and which gives up logical self criticism. That is to say, it is the type of thinking which is analogous and in some respects quite identical with the thinking we find in dreams, and in the autistic thinking of the schizophrenic who bothers as little as possible about actualities, and who thus fulfills his wishes in a state of megalomania or in persecutory trends, which is a result of his projection of his own incapacities into the outside world. It is this type of thinking that was named autistic; it is ruled by its own independent laws which depart from our realistic logic; this thinking does not seek for truth; it is preoccupied with wish-fulfillments. Accidental association of ideas, and most of all inner affective demands, take in many respects the place of realistic logic. They prevent the individual from deriving his associations from actual experience and following strict realistic logic.

Bleuler cites time and again the propensity of the medical man to believe what he wants to believe, to be motivated by economic success and therapeutic do-it-quickly methods. It is a kind of autistic empiricism in medicine that Bleuler attacks, which he calls "wearing the therapeutic necktie which happens to be the style of the moment."

While reading over the galley proofs of his book Bleuler came upon the fact that four or five years before him a booklet had appeared (already then in the fourth edition) written by someone named Bouget and called "*Quelques erreurs et tromperies dans la science medicale moderne*," and in a footnote to his text Bleuler called the reader's attention to this booklet; he remained impersonal and sought no priority rights.

Bleuler had no patience with this type of thinking in the practice of medicine.

The medical man, Bleuler believed, had no business to be the slave of "the need to feel comfortable on the part of the public"; he stressed the social and ethical demands which the medical man must impose upon himself. Bleuler raised his voice against the too generous and indiscriminate dispensing of various medicaments.

More than two centuries ago, Sydenham made the statement that the arrival of a jack-pudding [buffoon] in a small town might be more beneficial to the health of the inhabitants than the arrival of twenty jackasses laden with drugs. Sydenham was an able man and a great physician. I am deferring to the authority of his name, for I ascribe no value to scientific priorities. Sydenham did not know in his day of our modern drug industry, or he would have spoken of drug factories instead of jackasses.¹²

Bleuler considered certain experiments on rats without proper human controls a manifestation of purely (or impurely) autistic thinking in medicine. The highest form of one's relationship to reality is one's ability to state simply: This I do not know.¹³ "Careless thinking is oligophrenic and leads to error; autistic—to paranoia; our ordinary everyday thinking is a mixture of realistic and autistic trends."

As one of the examples of autistic manners, Bleuler spoke of those who fight Freud's psychology with relentless zeal, and pointed out that this psychology put the whole field of psychopathology on a totally different foundation, and that one finds this great change in the very writings of those who still believe that they have rejected Freud once and for all.¹⁴

Some of our psychiatric household terms Bleuler rejected as autistic mannerisms rather than realistic designations: so many believe that they designate something definitive by the term "psychopath"; in actuality no one has as yet established a proper concept of what a psychopath is. It is a negative designation of a general deviation from the normal. We ought not to look upon any striking characteristic of an individual as

¹² E. Bleuler. *Op. cit.*, 4th ed., p. 18.

¹³ *Op. cit.*, p. 90.

¹⁴ *Op. cit.*, p. 45.

psychopathic. Let us call him a schizophrenic, an hysteric or whatever he is; if we don't do this, then what is left is only the designation "psychopath," which tells us nothing about the nature of the deviation in question.¹⁶

With a striking boldness Bleuler pointed out the instinctive, intuitive psychological knowledge which so many medical quacks possess. Scientific medicine too was until recently in possession of this gift of intuition; unfortunately, the purely mechanical physical and chemical methods which make diagnostic work so much easier have also, however, made us turn away from the psychological.

The habit of making direct psychological observations, in the manner of a spontaneous, natural understanding of man, which even the uneducated possess, has been lost, and we behave as if we ought to defend ourselves against something mystical when we come in touch with the most important aspect of civilized man (the psychological). Psychic mechanisms are too complex for us to be able to reduce them to easily understandable and mechanically applied formulae, like chemical reactions. This is why there is a fear of the psychological in medicine.¹⁶

I may add that essentially this is still true today, despite our apparent acceptance of the psychological in medicine as evidenced by the popularity of the term "psychosomatic medicine." The general distrust of psychopathology on the part of medical men and medical students is I am afraid greater than the increasing popularity of psychiatry and the broadening of the psychiatric curricula in our medical schools would indicate.

Bleuler does seem to be still right today, more than we know. Apparently we have not yet solved the problem. It is not merely a matter of training alone. Perhaps psychiatric education must be more cognizant of the need for humanistic education, without which traditional scientific education as it is understood by positive sciences becomes, as Bleuler pointed out, an impediment in our methodological approach to human problems. The issue of integrating the subject of psychology as a humanistic discipline into the field of human knowledge, without mak-

ing psychology the maidservant and mimic of physics and chemistry, has been raised time and again throughout the history of scientific thought; Bleuler too brought it into focus. It is this issue that remains unresolved in our present-day, post-World War American psychiatry.

As I said before, the approach which might be termed "humanistic existentialism" offers some hope, and some of the European psychiatrists are now testing it successfully both in psychotherapy and psychopathology as a theory. The name of Ludwig Binswanger in Switzerland, an offshoot of the Bleuler tradition, comes to mind in this connection.

But this aspect of the solution raises a number of new problems which were not envisaged by Bleuler. It is highly important, for instance, to avoid slipping into a sterile personalism under the guise of individualism in psychopathology. It is also highly important to learn, and we still have a lot to learn in this respect, how to talk to each other without falling into the confusion of autistic conceptualism under the cover of a terminological screen.

This problem stood before us long before Bleuler in all its acuity and urgency. Said John Henry Newman almost a full half-century before Bleuler:

No power of words in a lecturer would be sufficient to make psychology easy to his hearers; if they are to profit by him, they must throw their minds into the matters in discussion, must accompany his treatment of them with an active, personal concurrence, and interpret for themselves, as he proceeds, the dim suggestions and adumbrations of objects, which he has a right to presuppose, while he uses them, as images existing in their apprehension as well as in his own.¹⁷

There is more than an appeal for semantic clarification in these rather contemplative, mid-Victorian words. It is the same appeal as Bleuler made when he insisted on direct human observations, through instinctive (intuitive) contact with your fellow men; I could call it an appeal for truly existential cooperation, taking all the time into account the living individual before you.

In this respect it is more than a coinci-

¹⁶ *Op. cit.*, p. 64.

¹⁶ *Op. cit.*, p. 18.

¹⁷ *Grammar of Assent*. Image Book. 1955, p. 37.

dence that the atheistic friend of Bleuler, Sigmund Freud, called the highest achievement of normalcy work and love, and that the scientific, observational empiricist Bleuler considered work-therapy (*Arbeitstherapie*) as the cornerstone of treatment. Here again I must point out that the term "occupational therapy" used by the English-speaking psychiatrist does not convey exactly the meaning that Bleuler had in mind. The words "occupational therapy" might connote a form of diversion, a form of "getting away from one's self" as the expression goes, while work-therapy as Bleuler described it in his book on schizophrenias meant to him explicitly the awakening of the autistic person to true productive creativeness, to overcoming his autistic proclivities.

It is this concern with the person in man that makes Bleuler stand out as one of the truest representatives of humanism in clinical psychiatry. To put it again in the words of Newman, purely formalistic considerations make man "attenuated into an aspect

or relegated to his place in a classification." Bleuler had no stomach for such attenuation. Therefore he stated: "I feel ever so much obliged to pay attention to the interests of the community and to follow the order of the State—without however ever losing sight of the individual." In the light of this careful avoidance of the sorry business of "attenuation" of the human individual, it is fitting to observe that as a result of many years of hard work in a mental hospital and hard thinking about man in sickness and in health, Bleuler came to the conclusion that "the special task of the educational influence of a mental institution is the habituation of the patient to be *free*" (*italics mine*).¹⁸

Thus the neutralistic Swiss in Bleuler ever strove to preserve the individual in man and, what is most important, his freedom—a freedom which neither state nor institution might impede. To Eugen Bleuler illness, the great constrictor of human freedom, should be treated in the service of true inner and outer freedom.

¹⁸ M. Bleuler. *Op. cit.*, p. 114.

RESPONSE TO FELLOWSHIP LECTURE ON EUGEN BLEULER

E. E. KRAFF, M.D.¹

In the brilliant and wise lecture with which Gregory Zilboorg has commemorated the one-hundredth anniversary of Eugen Bleuler he has rightly compared the great Swiss psychiatrist with the two outstanding men whose centenaries the psychiatric world celebrated in 1956: Emil Kraepelin and Sigmund Freud. He has also reminded us that Bleuler was in a way standing between Kraepelin and Freud, adhering in fact to Kraepelin's nosology and Freud's psychopathology at the same time.

I am afraid that in the minds of some the second proposition risks invalidating the first. "Between Kraepelin and Freud" . . . does that not sound like lukewarm eclecticism? And do eclectics—even the most distinguished amongst them—ever rank together with what Schopenhauer called the "*originaldenker*," the original thinkers? It would not be difficult to enlarge upon this argument. No doubt: it was Bleuler who coined the term "schizophrenia"; but was it not Kraepelin who laid the clinical foundations, and did not Bleuler himself recognize the fact in calling his famous monograph *Dementia praecox or the Group of Schizophrenias*? It is true: the terms "ambivalence" and "complex" were first used in the Burghölzli; but could they have been found if Freud had not seen the corresponding phenomena first? (One might even use Bleuler's own words (in the preface of the monograph) that "the whole idea of dementia praecox originates with Kraepelin" and that in respect of Freud's ideas he was only responsible for their "application" to schizophrenia.)

Let me answer the sceptics right away and tell them that Bleuler's genius lay in the field of "Ethos" rather than in that of "Logos." He could "stand between Kraepelin and Freud" and still remain original because he approached the problems of man not so much

with intellectual curiosity as with a feeling of human fellowship. As he observed his patients not as specimens to be dissected and filed but as persons to be respected and helped he had an immediate understanding for them which allowed him to give to the realities which Kraepelin and Freud had painted something like an additional dimension.

Of course, neither Kraepelin nor Freud were coldly curious or lacked all feelings of human fellowship; but it is hardly unjust to say that both were more scientists than physicians. Kraepelin, for instance, wanted to devote his life to experimental psychology and became a psychiatrist only because he had to earn a living. He always considered his psychological experiments his most valuable contributions to human knowledge, and as to his interest in therapy I can bear testimony that it was completely negligible. As to Freud, he admitted that he had "never really been a doctor in the proper sense," but he became one "through being compelled to deviate" from his original purpose (of becoming a physiologist). He regretted that his restricted material circumstances prevented him from taking up a theoretical career, and Ernest Jones recalls in his biography that Freud expressed "as far back as in 1910 . . . the wish with a sigh that he could retire from medical practice."

It is noteworthy that Bleuler's attitude was quite the reverse. When at the age of 29 he was appointed Superintendent of the Asylum of Rheinau he concentrated from the very beginning on plain doctoring, and so enthusiastically did he devote himself to this task that he went far beyond psychiatry into the field of general practice, attending not only the medical needs of his patients but also those of his personnel and of the villagers of Rheinau and going in this endeavour as far as actually arranging for a weekly operating session at which he performed quite alone even major operations. He became in fact a family doctor not only

¹ Address: 16, Parc Château Banquet, Geneva, Switzerland.

in the usual sense of the word, but also in being a father-image for everybody around him, patients as well as nurses and attendants. He ate with his flock, he worked with them, he arranged their parties, he shared in their amateur theatricals, sometimes he even administered their savings accounts, and so completely did he identify himself with his activity in the field of what today we would call social psychiatry that he was in the middle of planning the transformation of the village of Rheinau into a psychiatric colony of the Gheel type when the Zurich Government surprised him in 1898 with his appointment as Professor of Psychiatry and Director of the Burghölzli.

For the European scientist there is no greater satisfaction than obtaining "the Chair." Kraepelin did not really come into his own until he had been appointed Professor in Dorpat, and Freud resented it bitterly that the antisemitism of the Austrian authorities made it impossible for him to become a full professor. For Bleuler it was apparently a sacrifice to accept the professorial gown. This is at least the opinion of his son who, in response to a question of mine, told me recently: "After his moving into the Burghölzli . . . the possibility of fully giving himself to the life of his patients did not exist any more. All through his life he felt this painfully, and I believe that since I have known him there was always a certain resignation in his attitude towards the patients. He would have liked to come as close to them as before but it was not possible any more."

Of course, this does not mean that Bleuler actively disliked his professorial job. Somebody who abhors teaching cannot write a text book of so high a quality as his. Possibly at the beginning he was not a very brilliant professor. If one hears that in his first years in Zurich he sometimes based his lecture on a few pages torn out of a current manual one cannot be entirely out of sympathy with the Faculty of Medicine which had opposed his appointment. Later on his teaching performance was certainly more than adequate, and we have every reason to believe that he was quite happy with having the possibility of helping his students in their quest for knowledge. It is probable, how-

ever, that he never ceased to consider it more important to help his patients in recovering their health. We know after all that when, as a high school student, he decided to become a psychiatrist, he did so because he was aware that the peasant population of his canton (to which his own family belonged) was not too happy with its mental patients being in the hands of men who like Griesinger, Hitzig and Gudden, were not familiar with the "Züri-Tütsch" and because he wanted to satisfy the desire of his people to have not only erudite savants but also a real doctor. We have, moreover, the conclusive evidence of Bleuler's research orientation, the development of which can only be understood if one takes into account that as Ludwig Binswanger puts it: "The primacy of his life was practical reason" in Kant's sense.

Bleuler's fame is essentially based on his work on schizophrenia, and his most important contribution in this field was undoubtedly the profound analysis of the dynamic psychopathology of the schizophrenics. But originally the scientific interests of Bleuler had been very far removed from psychology proper. Apart from a few studies on the biology of the criminal in Lombroso's sense nearly all the papers he published in the first twenty-five years of his professional life were on neurophysiological, neurological and neuropathological subjects, and it would have been difficult to guess at that time that this young organicist was destined to become one of the most outstanding medical psychologists of his generation.

In my opinion it is quite evident how the change in Bleuler's research orientation came to pass. In the decisive years of his scientific evolution, in Rheinau, the vast majority of his patients were schizophrenics. His medical Ethos obliged him to make every possible effort to cure them. And in this connection he discovered not only that (using now his own words) "except for the treatment of purely psychogenic disorders, the therapy of schizophrenia is one of the most rewarding for the physician," but also that "at the present time, the only type of therapy that can seriously be considered for schizophrenia as a whole is the psychic method."

Since then we have of course learned seri-

ously to consider somatic methods too. There is no doubt that Bleuler, if he were alive today, would very much approve of this. The last time he participated in the discussions of the Swiss Society of Psychiatry he commented in fact on the chances of bodily therapy and said that in respect of the "cardinal question of finding the point where one could attack" he could only hope that the younger generation would be more fortunate than his own. But the unquestionable advances made in the field of somatic treatment have by no means diminished the need for a reasonable employment of the "psychic method." Insofar as they help the patients to regain a better contact with the outside world they have even increased it. Moreover, clinical experience teaches us that schizophrenics respond in a favourable way to the very fact of being cared for, and in making use of this reaction we are certainly very close to the "psychic method" Bleuler was employing.

Bleuler was indeed very far from recommending the psychotherapy of schizophrenia as we understand it today. He was convinced that "the symptomatology of the disease is dominated by the complexes," but he did not see how it could be influenced from that angle in a systematic way. "The only way," he said, "is to offer chance itself a great many opportunities so that it may seize one of them. If this is done at the right moment, a good deal can often be accomplished." Thus it has to be understood that he saw the most important aspect of occupational therapy in that it "offers the attendant personnel almost the only opportunity for close contact with the patients." In other words: his goal in occupational therapy was not to keep the patient busy, but to get near him and to give him the warming feeling of being cared for. Nothing is more typical of his approach than the little story he himself tells in his monograph: "In one of the hospitals I encountered a violent woman patient who was regarded as so dangerous that not less than four attendants at a time were permitted in her room. On Christmas Eve I took this patient along to the party at the hospital. On New Year's Eve she introduced herself as a singer; some weeks later she was released." But perhaps I should also report a story

which I heard from one of his pupils: Walking through the Burghölzli with his assistants, Bleuler was once shown some new material upon which very destructive patients could sleep completely naked. He immediately undressed and lay down on it because, as he said, "I cannot oblige a patient to lie on this stuff if I do not know whether it is adequate for a human being." Clearly, Bleuler's psychotherapeutic practice makes very good sense from the point of view of psychoanalytic theory, but the point I want to stress here is that it was practical far more than pure reason that allowed him to penetrate so deeply into his patients' unconscious.

It would not be difficult to show also in other spheres to what extent Bleuler's existence centered around his ability and his desire to respect, help and understand his fellow beings. I think it is a characteristic reflection of his own genius that amongst his pupils he had outstanding personalities as different from each other as for instance, C. G. Jung and André Repond, Karl Abraham and Eugène Minkowski, Abraham Brill and Ludwig Binswanger, Hans W. Maier and Hermann Rorschach to mention only a few. I cannot resist the temptation to tell in this connection an anecdote which shows very plastically how little authoritarian he was in his relations with his collaborators. When Françoise Minkowska, Eugène Minkowski's brilliant wife, was a young resident at the Burghölzli, she once showed her indomitable temperament by loudly criticizing Bleuler's way of examining foreign students. When Bleuler heard of her comments he called her and asked her to sit in an adjoining room next time he had to examine a foreigner and then to tell him in a concrete way what errors he might have committed. André Repond, whom I recently consulted about Bleuler's attitude in respect of his assistants, called it "very fatherly and full of understanding," and the little story I have just related is certainly very apt to show this aspect of his interpersonal behaviour. It is perhaps even more important, however, that Bleuler was able to act not only as an understanding father, but, if I may say so, also as a helpful older brother. All his pupils

praise, in fact, his preparedness to enter into a scientific discussion on a footing of complete equality even with his youngest residents, and Ludwig Binswanger responded to my query in this respect by calling Bleuler's attitude "democratic in the highest sense." This is a very interesting formulation on which I should like to make a few comments.

Bleuler came from Swiss peasant stock; in other words, he was the true son of a people justly famous for having developed a type of society in which the democratic equality of rights and duties is based on a deep respect for rugged individuality and on a century-old tradition of mutual assistance in case of need. I do not think that it detracts

in any way from our admiring appreciation of Bleuler's greatness if we discover in his genius the principal traits of the genius of his nation. I should say that in my opinion it even increases it just as I believe it heightens the stature of a Lincoln that we can consider him the ideal type of an American. I do not know whether this kind of genius can only grow in a democracy, but I am sure that it is nowhere better understood and better loved. Therefore it seems very fitting to me that Bleuler's centenary should be commemorated precisely in these United States. The American Psychiatric Association ought to be congratulated on its intuition in choosing this subject for this year's Fellowship Lecture.

MURDER BY ADOLESCENTS WITH OBSCURE MOTIVATION

A. WARREN STEARNS, M. D.¹

In the early days of society, treatment of crime was entirely instinctive. This is reflected in such sayings as "An eye for an eye and a tooth for a tooth," "He who sheddeth man's blood, by man shall his blood be shed," and so forth. The motive was revenge, and it depended upon an instinctive reaction. Later on, as man became less savage and more a man, the theory of the deterrent effect of punishment gradually appeared. It postulated that society could be immunized against crime through a fear generated in all hearts that, if they sinned, they would suffer. Still, they sinned. E. B. Wilson has said, "Punishment is no good after you are sick. It may be a good way to condition children."

Latterly, there has developed an interest in trying to do something with individual offenders. This was at first called *correction*, later *reformation*, now *rehabilitation*. During the past century, and more particularly the past half-century, with the development of psychiatry, there has also developed an interest in the makeup of the individual offender. Psychiatrists have dabbled in criminology, but on the whole few serious systematic studies have been made. For the most part, psychiatrists and those working under their direction have tried to classify criminals within the categories set up for the classification of insanity. This attempt has been largely unsuccessful. It has resulted in a much hypertrophied group of personality disorders, which has included so many diverse elements that it is hardly fit to be called a group at all. Originally, its use was confined to those individuals who from early childhood had shown deviations in development and behavior. Latterly, it has been applied to cases where one single act was all that there was to go upon without any attempt at picturing a clinical entity. It has seemed to the writer, after many years of contact with crime and much reflection on the matter, that it ought to be possible to establish clinical syndromes in criminology

comparable to those in medicine, although not in any sense identical. When physicians classified certain types of sickness as fevers, it was quite an advance. It at least brought cases together which ultimately turned out to be infectious. When the group was broken down into measles, scarlet fever, diphtheria, typhoid and so forth, it laid the way to further understanding and, as it turned out, specific treatment.

In the opinion of the writer, if psychiatrists are to seriously undertake a study of criminology, they must first develop some sort of classification. It is too much to hope that this could be developed full-grown, giving the type of diagnosis and treatment now available in medicine, but at least a start can be made. With this in view, a series of cases is presented with the suggestion that they represent a clinical syndrome comparable to some of those in medicine.

It has long been recognized that profound changes take place in the human body during the period of adolescence. It has also been recognized by some, although not admitted by all, that these changes are frequently associated with alterations in behavior. A substantial portion of students have associated these alterations in behavior with changes in body chemistry, although latterly there has been some tendency to attribute them to environmental pressures or deficiencies. It is not my purpose to debate this matter, for the issue is not important in the thesis which I hope to develop. Enough to identify adolescence as a period when extraordinary things may take place: these may be the arousal to great events; the simple revolt from parental or adult control; or suicides without motivation, which I have recently published(1, 2). Murder is comparatively rare at this period. In my previous study, only 2% were under 21 years of age(3).

I wish to describe briefly a group of adolescent murders for which no motivation has been found and which seem to have certain elements in common. These cases further illustrate the value of a categorical arrangement of criminals. I have done what I could

¹ Address: Billerica, Mass.

to conceal the identity of the cases for obvious reasons but have tried not to mutilate the picture too much.

CASE 3428.—This is a 15-year-old boy of excellent reputation. His mother was psychotic, and he lived with relatives. He was a student in junior high school, and there is nothing in his record to indicate that he was anything except a fine specimen. He had been attentive for some little time to a 14 year old girl, a schoolmate. They had been together more or less, had kissed on at least one occasion, but there had been no overt sexual experience. They rode out to a ball game on his bicycle. She was scantily clad and sat facing him on the handlebars. In the early evening they started home. After going a short way, they stopped at a park; she dismounted, he remained astride the bicycle. He drew a pistol from his pocket, a recent acquisition to his collection. His grandfather was interested in guns and occasionally sent him a specimen. He had carried it for some time, and at least on one occasion he had fired it. He showed it to her. She said, "Don't shoot me," whereupon he pulled the trigger 4 times, the bullets passing through her chest, one through the aorta, killing her instantly. He rode away for a while, and then came back to give himself up.

Although every possible theory was exploited, no motive was ever found. He said he didn't know why he did it. It was an impulse. Repeated examination revealed nothing extraordinary about his personality. Dr. Abraham Myerson, who studied him at the time, felt that he was an incipient case of dementia praecox. He and I were employed together and talked over the matter at length. In general, his diagnosis of incipient dementia praecox was based on the supposition that there must be some profound pathological process going on to account for the crime. The boy pleaded guilty to second degree murder and received a life sentence. Upon admission to the prison, he was again thoroughly studied and was considered a model American boy. The only deviation he showed was slight stammering. About 2 years after his admission to the prison, he cut his elbow with a razor blade, leaving a note stating, "This is a suicide. May I be buried beside whom I now join." At the bottom of the note he had left his fingerprints in blood. He was sent to a hospital and in a few days was entirely well. There has been no repetition of this depressed episode. In the last 10 years, he has acquired considerable formal education, developed great talent in art, and is considered to be a healthy, normal young man. A recent review of his case shows an I.Q. of 112. There have been no conduct infractions during his 12 years in prison, and psychiatrists state: "There was no psychiatric process present. Does not appear schizophrenic."

CASE 3811.—This is the case of a 13-year old boy with excellent reputation. It was generally said that he was one of the last persons who would be suspected of doing wrong. He was a newsboy and went to the house to collect for the papers. He re-

ceived the money and started along; then he turned back, why he knew not. He knocked at the door and as the 41-year-old victim came to let him in, he asked for a drink of water. He stepped inside, she turned to get the water, and as she passed it to him, smiling, he hit her on the head with a milk bottle, knocking her to the floor. She was unconscious but apparently not dead. He slipped a laundry bag over her head, pulled up the strings and strangled her. She was clad in white shorts and a halter only. He stuck a knife into her abdomen, saying that he had been told that, if a person was dead, he would not bleed. He also wrapped a towel around her neck. He then ransacked the house taking nothing, returned to a group of boys playing ball, and then went home. No one noticed any change in him whatsoever. Four days later, the victim's daughter coming home found her body on the floor. Persons had seen him go to the house; he was questioned and freely admitted his guilt. He assigned no motive, and no motive was ever discovered. He said an impulse came over him. He pleaded guilty and was sentenced to prison for life. During the 10 years of his prison sentence, he has grown to be a very large man. His conduct has been exemplary. He has studied hard and hopes to get out sometime, although he once told the writer that, if there was any chance of his ever doing that sort of thing again, he would gladly remain in prison the rest of his life.

CASE 4828.—This is an 18 year old, whose family was in comfortable circumstances; he was bright but inattentive in school, so that he did not graduate from high school. He was attending private school where he did little or nothing. He was ardently courting a 17-year-old girl. He had his own car and was something of a traffic problem, but on the whole had an excellent reputation. He had a tear in his raincoat; went to one or two dry cleaners to have it fixed. He then went to a dressmaker whom he had seen once with his mother 2 years before. He knew where she lived, as he had driven his mother there. He asked her to repair the tear in his raincoat. This she did; charged him 50¢; he gave her a dollar bill, and, as she turned, he seized her, strangled her, killing her with his hands. He then went to the sewing room, got some cloth panties and put them around her neck and tied a very tight knot. He next went to the kitchen got a rolling pin and hit her several times on the head. He then got a butcher knife and plunged it into her heart. Then he got a piece of cloth and tied her feet together. He later stated that as he emerged from the apartment, an awful feeling came over him, "What have I done?" He was restless, uncomfortable; went home; could not stay there; went out with some girls, where he repeated the whole event. The girls did not believe it, and he finally told them that it was true and that he was a murderer. Still, they did not believe it. The next day he drove about with a girl and was finally arrested. Here again, no motive was ever determined. He pleaded guilty and received a life sentence.

CASE 4878.—An 18-year-old boy from a good home with an excellent reputation killed a school-

mate. He had failed some courses in high school and was repeating. There is no other suggestion of aberrant conduct. He owned a large bayonet or dagger which he sometimes carried. On the night in question, he went out to walk. He saw his girl friend through a window, returned to his house and got the bayonet. He then went to where the girl friend was babysitting and knocked on the door. When she came to the door, he fell upon her with the bayonet, stabbing her 46 times, thereby killing her. The baby was in a crib nearby, and he stabbed him several times. He was not apprehended for several days. He was a bearer at the girl's funeral, but when accosted made a complete confession. He said he did not know why he did it. The impulse came over him. He had much psychiatric examination, being called *dementia praecox*, psychomotor epilepsy, personality disorder, etc. He was sentenced to death, but this sentence was finally commuted to life by the governor and council. He has shown no evidence of nervous or mental disease since his confinement, and neither has any motive for the crime ever been elucidated.

These 4 cases have certain elements in common, enough I believe to establish a clinical syndrome. The perpetrators have all been adolescent males, their reputations have all been uniformly good, the victims have all been females—two scantily clad, and the crimes have been wanton and ferocious. No motive has ever been established. When such a murder case occurs, I think it fair to assume that the same pattern will be present as in the cases above. It has been assumed quite largely that there has been gross mental disease to account for such crime. It has further been assumed that these persons should be confined for life, that there is indication of some morbid quality which would make it dangerous to ever release them. Having this in mind, I wish to pre-

sent one further case in which the victim did not die, and therefore the perpetrator received a reformatory sentence, was subsequently released on parole, and has shown no evidence of conduct disorder since.

CASE 4955.—This boy was 13 years old and in the 7th grade, having repeated the 4th. He was a non-reader; came from a very disordered family, the father having been once arrested for indecent exposure. He had shown no gross conduct disorder until the present incident. He was building a tree house in the woods near his home. His father would not get him tools, so he went to a hobby shop and stole a knife and a hatchet. The knife was in a sheath which he carried on his belt. While working on the project, he saw a girl his own age go by. He did not know her but walked out to her, and they looked at each other. She said, "I won't bite you." He said, "I won't bite you." He invited her into the woods saying he had a surprise for her. When a little way from the street, he told her to turn around, whereupon he plunged the knife into her back. She fell backward, and he grabbed her, and there were one or two slight cuts on her face and neck. Just what happened then is not entirely clear, but he was arrested and made a complete confession to the police. He is said to have told the police that he wanted to see her breasts.

He was friendly and cooperated with me. The crime appears to be the result of an impulse. We can infer a sexual motive but cannot demonstrate it. He does not show any evidence of psychosis or gross mental disease. His period in the training school was uneventful. School behavior was very good, and he made a good adjustment. He is now in high school.

THE UNLOCKING OF WARDS IN MENTAL HOSPITALS

L. C. HURST, M.B.¹

The problem of eliminating locked doors in all mental hospital wards has been under consideration by psychiatrists in Britain for some years. Dingleton Hospital, Melrose, led the way and has been completely unlocked since 1949. Nottingham City (Mapperly) Hospital followed suit by opening all its wards, as did Warlingham Park Hospital more recently. The latter had only 2 locked wards out of a total of 23 for some 12 years previously, however. Warwick Hospital is also completely open now.

Nevertheless, references in the literature are scanty and the method of opening locked wards has been expounded somewhat vaguely. Little has been done in the way of controlled observation of the results of opening. Bell(1, 11) holds that a satisfactory stage of nurse-patient relationship must be reached as a preliminary to unlocking the wards and that mechanical restraint, seclusion and tube-feeding must be absolutely prohibited. He also lays emphasis upon the education of the public, and exhorts his staff to take a full part in local activities. Koltes(5) maintains that patients must be encouraged to take the attitude that the "hospital is theirs" and that behaviour will then improve and the opening of wards follow as a matter of course. This change of attitude is to be brought about by an intensive group therapy programme, constructive activity in which the patients feel that their work is not exploited and a nonauthoritative role on the part of the staff as regards the patients' everyday life. These ideas are also expounded to the visitor to Warlingham Park Hospital. Rees and Glatt(7) however describe a system of habit-training and occupation employed in a ward of deteriorated patients and report that the use of methods such as these have enabled the wards to be opened at Warlingham Park Hospital. Experience at Mapperly Hospital is in accord with this(10).

The results of ward opening are even more

vaguely defined. Bell(1) says that such a measure leads to "complete lack of tension" in both patients and staff, whereas several locked wards are retained at Netherne Hospital because the staff believe that a closed ward has a sedative value for patients with severe anxiety(5). Bell(1) quotes the case of 3 epileptics with a diminution in the number of fits after opening. He also states that wetting, soiling, destructiveness and refusal of food have almost disappeared, except on the senile wards. Even the increase in the voluntary admissions to Dingleton Hospital in the years after the introduction of open doors (and the establishment of the National Health Service) is cited as an indirect result of opening.

Both Macmillan and Bell(10) agree that the paranoid patient is less inclined to attempt to abscond from an unlocked ward.

It is peculiarly easy in psychiatric practice to conclude that certain procedures produce various changes which happen to have emerged in association with their application. Wittgenstein(8) offers a healthy corrective; "Es können alle Kombinationen der Sachverhalte bestehen, die andern nicht bestehen."

Most of the preparatory requirements for ward opening quoted above rest upon 2 assumptions. First, that well-integrated escapees will provide the principal problem in the opened wards, and second, that the regressed, confused schizophrenic will be amenable to such influences.

In view of this, experience recently gained at Shenley Hospital, near St. Albans, would seem to be relevant. Female Division B comprises 752 beds. Of these, 360 were in locked wards until last year, contained in a block of 6 wards and an insulin shock therapy ward.

Between May and September 1956, 4 of the wards on the block were opened. Neither intensive group therapy nor a programme of occupational therapy on the ward preceded this step. (A small group of 7 psychotics had been having group therapy sessions for several weeks before their wards were opened and weekly sessions involving

¹ Senior House Officer, Shenley Hospital, Hertfordshire, England.

all the patients on the semi-refractory ward have since been instituted.) No changes were made in the method of running the wards prior to their being opened.

As each pair of wards share an airing court, it was necessary to undertake the opening of 2 wards at a time.

The 2 wards first opened were respectively an infirm ward of 50 beds and a ward of 57 beds containing for the most part well-integrated patients, 14 of whom worked in the hospital utility departments. These wards and their airing court were opened on May 19, 1956, and raised relatively few problems subsequently.

Before opening the second pair of wards—a semi-refractory ward of 52 patients and a ward of 55 patients, for the most part degraded and including 25 epileptics—14 patients had to be transferred to the remaining locked wards. Of these no less than 12 were deteriorated schizophrenics of under 60 years of age. There was one case of senile dementia and one blind mental defective. The semi-refractory ward was opened (via the adjoining open ward) on September 26, 1956, and the other ward (similarly) on the following day. On the 29th the airing court was thrown open.

During the first 4 weeks of unlocked doors, 11 patients had to be brought back to the semi-refractory ward, and 5 to the epileptic ward. (The corresponding figures for the 4 weeks preceding opening were 2 and 3 escapes respectively.)

Of these, no less than 10 were deteriorated schizophrenics under 60 years of age, two were deteriorated schizophrenics over 60 (one was found dead). The remaining 4 were non-deteriorated schizophrenics. Four of these patients were subsequently transferred to the locked wards. All of these latter were deteriorated schizophrenics under 60.

DISCUSSION

Several conclusions have been drawn from this operation which might be of value for those contemplating opening wards.

The first, perhaps surprising, fact emerging is that the well integrated patient presents little problem; the paranoid or manic patient often responds well to ward opening.

Those patients who have been formerly noted as escapees often abscond no more frequently than they did before the opening. Also, the paranoid cases may be much improved in this and other respects by means of chlorpromazine.

Senile dementers provide a problem, but a small one. The principal difficulty occurs with the deteriorated, confused schizophrenic. These patients are often not merely troublesome, but are of some danger to themselves when they wander off an open ward. They do not respond well to group psychotherapy, although they may do so to regular occupational therapy and simple manual tasks under constant supervision (4, 6, 7). Certainly, such a programme provides supervision and tends to diminish the time during which they are wandering aimlessly around the ward garden, and perhaps out of it. There is some evidence that routine occupation does reduce the tendency of this type of patient to abscond (6).

In retrospect it would seem that a programme of occupational therapy for these patients might well have preceded ward opening by some months.

The need for controlled studies of such changes as ward opening is very great. A belief that patients and staff have improved socially may be merely due to projection on the part of the psychiatrist. It is difficult to obtain such controlled studies, as ward opening is inevitably accompanied by the transferring of degraded patients or by other measures such as an occupational programme. These will have an unassessed effect.

Of course, this consideration applies with equal force to the supporters of locked wards. Incarceration is unpleasant—it is society's chief deterrent—and most patients do not emulate the subjects of Honorius in "contemplating their new freedom with surprise and terror" (3). (One disgruntled patient did however remark, the day after her ward had been opened; "They've opened the doors; anyone can get in.") The onus would certainly appear to be on the supporters of locked wards to prove their case.

One thing that does appear possible is that the familiar, deteriorated, confused schizophrenic of the mental hospitals would

never have reached that stage had he spent his hospital life on an open ward. The removal of all contact with the outer world might reasonably be postulated as the principal precipitant of his condition. If this should be the case, the problem presented by these patients would be a temporary one. A reliable wire-mesh fence surrounding the hospital precinct—sufficient merely to deflect aimless wanderers—and a porter at the gate would seem desirable, at all events in the early days of open wards. These conditions prevail at Warlingham Park Hospital, but not at Dingleton Hospital. In both all the wards are unlocked. At Netherne Hospital, where 5 closed wards have been retained, the hospital grounds are open to the surrounding countryside.

SUMMARY

Consideration is given to the problems raised by the unlocking of the chronic wards in mental hospitals. The deteriorated schizophrenic, who has spent many years in the hospital, provides most of the difficulties. Attempts to employ this type of patient in small groups of 10 to 18 have produced good results (7, 6) and afford adequate supervision. The need for, and difficulties of, ob-

jective assessment of the effects of ward opening² are emphasised.

A STUDY OF THE EFFECTS OF L.S.D.: PHYSIOLOGIC AND PSYCHOLOGICAL CHANGES AND THEIR INTERRELATIONS

ALBERTO DI MASCIO, M. A., MILTON GREENBLATT, M. D., AND ROBERT W. HYDE, M. D.¹

In a previous experiment at the Boston Psychopathic Hospital it was shown that changes occurred in various parameters of the autonomic nervous system subsequent to the administration of Lysergic Acid Diethylamide in a dose of one gamma per kilo of body weight (1). Utilizing a polygraph as a means of recording the physiological variables, differences in the patterns of physiological reactions of the autonomic nervous system were observed between days in which L.S.D. or a placebo were administered.

The purpose of this study is to utilize this polygraphic procedure of data recording to investigate:

1. The changes in the autonomic nervous system which occur over the course of the day subsequent to the administration of L.S.D.

2. The relationship between the course of these physiological changes and the course of the behavioral and emotional changes.

EXPERIMENTAL METHOD

Apparatus: An eight channel Offner electroencephalograph converted to a polygraph, a recording instrument which allows for continuous and simultaneous recordings, was used. The apparatus was in a room adjoining the sound-proof, temperature-controlled room in which the subjects were placed during recording sessions. A one-way-vision mirror and an audio system allowed for complete observation during recordings. By means of wire leads attached to the subjects the following physiologic parameters were recorded: the EKG as a measure of heart rate, respiration, finger skin temperature, and the muscle tension recordings from the frontalis muscles. In addition systolic and diastolic blood pressure and pupil diameter were recorded.

Subjects: The subjects were 6 male col-

lege students, 24-28 years old and weighing 150-180 pounds, paid volunteers.

Procedure: For each subject there were 2 observation days; one of these days the subject received one gamma of L.S.D. per kilogram of body weight and on the other a placebo was given. The schedule for each day consisted of a series of 5 fifteen-minute recording sessions. The first recording session took place immediately preceding the administration of the drug, with subsequent sessions starting 1½, 2½, 4½, and 7½ hours after the L.S.D. was taken.

During each recording period the subject was comfortably seated, by himself, in the observation room and was connected by wire leads to the polygraph. The subjects were requested to refrain from any excessive movements throughout the sessions. At the end of each session pupil diameter (under standard lighting conditions) and blood pressure were determined.

In the interim between recording sessions the subjects were studied by another group of investigators who observed the social and psychological effects of L.S.D. Their observations on the types and/or intensity of behavioral changes manifested by the subjects, along with the subjective expression of various symptoms and their intensity, were recorded over the course of the day. Control and experimental days were kept as similar as possible.

ANALYSIS OF DATA

A. Physiological Data.—For each subject the following measures, derived from the physiological recordings, were obtained for each session of both control and experimental days:

1. Heart rate mean; 2. heart rate lability; 3. respiration rate; 4. respiration rate variance; 5. inspiration/respiration ratio; 6. I/R ratio variance; 7. finger skin temperature level; 8.

¹Address: Boston Psychopathic Hospital, 74 Fenwood Road, Boston 15, Mass.

muscle tension level; 9. systolic blood pressure; 10. diastolic blood pressure; 11. pulse pressure; 12. pupil diameter.

To adjust for day-to-day variations in the level of these physiological variables, to aid in eliminating individual variations, and to correct for the variations which normally occur in these variables during the course of the day, the following methods were employed:

1. All physiological data were dealt with in terms of the amount of deviation (expressed as a percent) from the first recording session of the day. This procedure aids in correcting for day-to-day variations in the level of physiological measures and individual variations in initial level.

2. The deviation of each variable in each recording session from the first recording in the control days gives an estimate of day to day variations that normally occur. These variations which may contaminate the effects of L.S.D. are graphically presented side-by-side with the deviations noted in each variable on the L.S.D. days, so that the amount of deviation for the corresponding periods and variables could be compared.

The combination of these two procedures allows us to note, over the course of the day, changes in the physiological variables due primarily to the L.S.D. effects.

B. Psychological Data.—The rate of onset, peaks, fluctuations and intensity of symptoms of subjects administered small doses of L.S.D. were evaluated by clinical psychiatric examinations and by observers who studied the subject throughout the experimental day. The symptoms, based on the subjects' verbalized reports and overt actions, were grouped as somatic, mental, perceptual or social. However, since an increase in symptom intensity could occur that might not be verbalized or observed, a method previously devised (2) for recording the subject's viewpoint, his own evaluation of his L.S.D. reaction was used. The technique adopted consisted essentially of a simple histogram charted by the subject at the end of each experimental day. The extent of the

deviation from normal was indicated by each subject along a vertical axis consisting of 4 reference points: normal, mild, moderate, and severe.

Instructions for filling out the symptom graph were general. The subject was asked to give his own evaluation of the symptom intensity he experienced for the full day beginning with the moment the drug was taken. The basis for the comparison of changes was 1. the previous hour and situation and/or 2. his subjectively felt "normal" state. The quality or characteristics of the changes with reference to specific symptoms is a uniquely subjective matter. For that reason the standards or criteria for symptoms was structured in the form of an open-ended question. A space was provided for comments by which the characteristics of the peaks, changes and duration of the drug effects could be specified and elaborated by each subject.

RESULTS

A. Physiological.—For each physiological variable analyzed, 2 charts are given. The first chart shows the average ² variations that occurred over the course of the control day and the second chart shows the average variations that occurred over the course of the L.S.D. day.

1. Heart rate.

a. *Control day.*—The mean heart rate tended to remain quite stable throughout the day with the rather small changes that did occur (+05% maximum) showing a steady slow rise.

b. *L.S.D. day.*—During the second recording session (the first one after the drug had been administered), there was a decided increase in the heart rate which averaged about 11% higher than the control period rate. This increase continued until the fourth recording session when the peak increase of 18% was noted. The last recording session

²It is important to note that these are average values. Individuals differed somewhat in the degree of reactivity of the various autonomic systems. The relationships between these variations and personality structures will be the topic of a subsequent paper.

FIG. 1.—Heart Rate.

saw the beginning of a return towards the original heart rate level since the increase dropped from 18 to 10%.

2. Heart lability.

a. *Control day*.—The lability of the heart was not greatly altered through the day. The maximum variation from the first recording session occurred in the fifth session when a 9% increase in lability occurred. The small variations during the other sessions presented no consistent pattern.

b. *L.S.D. day*.—there was a gradual drop in the heart lability (*i.e.* it became more stable) until the fourth session when a sudden decrease of 28% was noted. During the last session the heart lability began to return to normal, as evidenced by the fact that the lability decrease was now only 14%.

3. Systolic Blood Pressure

a. *Control day*.—Very little change in systolic blood pressure was shown throughout the day, the changes never exceeding $\pm 2.8\%$.

b. *L.S.D. day*.—The systolic blood pressure rose until the third period (2½ hrs. post drug administered) when an increase of 12% was noted. A return towards the baseline tended to occur in the subsequent recording sessions.

4. Diastolic Blood Pressure

a. *Control day*.—The largest change (an increase) in the diastolic blood pressure noted during the day was only about 1.5%.

b. *L.S.D. day*.—The diastolic blood pressure rose until the third period (an increase of 10%). It then returned to the baseline by the next session and in

FIG. 2.—Heart Rate Lability (D-score values).

FIG. 3.—Systolic Blood Pressure.

the last a decrease (-2%) in the blood pressure was exhibited.

5. Pulse Pressure

a. *Control day*.—The pulse pressure dropped (-7%) in the first session and then tended to return towards the baseline mean during the next 2 sessions. The last session was featured by a drop in pulse pressure of 9% . In general the pulse pressure was below the control period mean throughout the control day.

b. *L.S.D. day*.—The pulse pressure on the L.S.D. days showed an increase until the fourth session ($+9\%$, $+16\%$, $+19\%$) and then a slight lowering in the last session towards the baseline ($+18\%$).

6. Muscle Tension

a. *Control day*.—A continued and progressive relaxation of the activity

recorded from the frontalis muscles was exhibited on control days (-16% , -18% , -24% , -26%).

b. *L.S.D. day*.—The muscle tension increased on L.S.D. days reaching the peak of tension in the third session ($+33\%$) and then showing relaxation in the latter sessions (returning almost to the mean baseline value ($+06\%$) in the last session).

7. Pupil Diameter

a. *Control day*.—The size of pupils changed very little during the control days and the variations noted were of a constriction nature.

b. *L.S.D. day*.—Pupil diameters, on L.S.D. days, were featured by a rapid and large ($+53\%$) dilation. By the fourth session they began to return to their original size although they were

FIG. 4.—Diastolic Blood Pressure.

HOURS AFTER DRUG ADMINISTRATION

FIG. 5.—Pulse Pressure.

HOURS AFTER DRUG ADMINISTRATION

FIG. 6.—Muscle Tension.

HOURS AFTER DRUG ADMINISTRATION

FIG. 7.—Pupil Size.

FIG. 8.—Skin Temperature.

still dilated (+24%) at the end of the experiment.

8. Skin Temperature

a. *Control day*.—The pattern of the skin temperature variations, small as they were, (+09% to -07%) showed a rise in the second session and then a continual, though moderate, lowering in the following sessions.

b. *L.S.D. days*.—The skin temperature in L.S.D. days showed a trend towards decreasing, reaching the lowest level (-09%) in the last period.

9. Respiration rate

a. *Control day*.—There was a slowing down of the respiration rate (10%) from the first to the second session, then a speeding (4-5%) of the rate until the last session when a sharp slowing (13%) was observed.

b. *L.S.D. day*.—The respiration rate

pattern became more consistent, with the rate speeding up (8%) in the first post-drug session and then slowing continually until, during the last session, it was slower (3%) than the pre-drug rate for L.S.D. days.

10. Variance of Rate of Respiration

a. *Control day*.—There was little change in the variance of the respiration rate until the last session when a large increase (+97%) in the variability occurs.

b. *L.S.D. days*.—In the first post-drug session the variability was doubled (+197%), followed, in the succeeding sessions by a progressive return towards the control session variability level (+168%, +125%, +35%).

11. Inspiration/Respiration Ratio

a. *Control day*.—The I/R ratio showed a slight decrease in the second

FIG. 9.—Respiration Length.

FIG. 10.—Variance of Respiration Length.

and third sessions (-3 to 5%) and then returned to the baseline for the remainder of the experimental sessions.

b. *L.S.D. days.*—The I/R ratio showed a gradual and continued increase from the first session throughout the day, reaching a maximum in last session ($+16\%$).

12. Variance of I/R ratio

a. *Control day.*—The variability of the I/R ratio was decreased during the second and third sessions of the control day (-48%) and then increased towards the initial level in the following sessions (-21% , -7%).

b. *L.S.D. days.*—The variability of the I/R ratio was doubled in the first post-drug session and almost trebled in the second. After reaching this peak of variability, the I/R ratio variance re-

turned towards the baseline in the next 2 sessions.

B. *Psychological.*—For a comprehensive description of clinical symptomology, over the course of the day subsequent to L.S.D. administration we refer the readers to S. Salvatore's article, "Progression of Effects of L.S.D." (3). For purposes of the present study it should be noted that the subjects reacted in an individual manner in terms of type, quality, and intensity of symptom formation. Overall, however, they showed a similar pattern of reaction such that: 1. symptoms (usually of a somatic nature) began to appear within the first hour after L.S.D. and were felt as mild or moderate in intensity; 2. during the next hour an increase in the number of clinical symptoms occurred, with an intensification of feeling of deviation from normality and some change in symptom

FIG. 11.—Inspiration/Respiration Ratio.

FIG. 12.—Inspiration/Respiration Ratio Variance.

quality—from somatic to predominantly ideational and perceptual distortions; 3. the peak deviation from normality was felt from the second to the fourth hour, with feelings of unreality and confusion being most prevalent; 4. these symptoms subsequently began to lose their strength, gradually diminishing in frequency and intensity until the end of the experimental day (8-9 hours after L.S.D. was administered).

CORRELATION OF CLINICAL AND PHYSIOLOGICAL EVENTS

The incidence and intensity of behavioral deviation as evidenced by the observer's reports and by the subjectively perceived symptoms coincided through the day, in general, with the incidence and intensity of physiological deviation. Both indices began to show changes within the first half hour, reached a peak of deviation between the third and fourth hours, and returned to the pre-drug level by the eighth hour. It is significant that these changes occur concomitantly, thus emphasizing the Cannon principle of simultaneity of emotional expressions and physiological functioning.

DISCUSSION

The reactions exhibited in our measures of the autonomic nervous system can be explained by a general sympathetic excitation that reached a peak between the third and fourth hours after the administration of L.S.D.; subsequently there was a gradual decline in sympathetic excitation by the

eighth hour, returned to the pre-drug level of activity. Three exceptions to this were noted in that the pulse pressure, the skin temperature and the I/R ratio reached their peak of deviation during the last recording session (the eighth hour after L.S.D.) and showed little tendency to return to the initial level.

The latter phenomena may probably be ascribed to the fact that autonomic nervous system measures are more sensitive as well as more objective than psychological indices. Thus after psychological effects and most of the physiologic reactions of the drug have subsided, residual changes not detectable by other means, may be demonstrated.

In psychotic subjects in whom sympathetic tone and high physiologic reactivity predominated (associated with increased anxiety states) it has been demonstrated that following lobotomy there is a decrease in sympathetic tone (drop in heart rate, more reactive heart, decrease in I/R variability, etc.)—which is associated with decreased anxiety, improved social adjustment, and improved intellectual functioning.

Essentially, this is what occurs with L.S.D. Subsequent to the administration of the drug, severe personality disturbances are produced with a concomitant increase in sympathetic tension; as these disturbances were reduced the sympathetic tone decreased and tended to return towards the pre-drug "normal" level.

The question may be asked, "Is an increase in sympathetic tension a necessary physiological concomitant of psychosis?" Our

studies would indicate that this may be the case.

SUMMARY

The physiological and psychological changes throughout the day subsequent to the administration of Lysergic Acid Diethylamide were recorded and analyses made of their interrelations. The Harvard Polygraph was used to simultaneously and continuously record heart rate, respiration, skin temperature, blood pressure, and muscle tension. Recordings were made under resting conditions immediately before and $1\frac{1}{2}$, $2\frac{1}{2}$, $4\frac{1}{2}$, and $7\frac{1}{2}$ hours subsequent to L.S.D. administration.

Physiologically, a general sympathetic excitation resulted, which reached a peak of tension in 3 to 4 hours and then gradually returned to the pre-L.S.D. level by the eighth hour. Heart rate increased and became more stable, systolic and diastolic blood pressures were elevated, pulse pressure rose, muscle tension mounted, skin temperature tended to drop, breathing became faster and more

variable, the inspiration/respiration ratio decreased and became more variable, and pupillary dilation occurred. No such drastic changes were noted in the control (placebo) days.

Changes occurred psychologically that paralleled the physiological changes. Deviation from "normality" both behaviorally and subjectively was most pronounced, in number of symptoms expressed and intensity of expression, about 3 to 4 hours after L.S.D. administration and gradually diminished until the eighth hour.

Some of the implications of this study are mentioned and the similarity between the sequences of events post-L.S.D. with the changes pre-post lobotomy are discussed.

THERAPEUTIC AND TOXIC EFFECTS OF CHLORPROMAZINE AMONG 3,014 HOSPITALIZED CASES

REUBEN M. CARES, M.D., EDWARD ASRICAN, M.D., MAURICE FENICHEL, M.D.,
PAUL SACK, M.D., AND JEAN SEVERINO, B.A.¹

Therapeutic response, side-effects and toxicity among 3,014 patients on chlorpromazine were studied during an 18 month period in a mental hospital with an average census of 9,200. The findings bear on the relation of moderate dosage to a low incidence of jaundice and clinical side-effects. Serial laboratory examinations may have been instrumental, through clinical awareness, in minimizing the severity of hepatic and/or leukocytic derangements. The large numbers of cases and laboratory tests lend themselves to an adequate statistical evaluation.

A few months after Winkelman's publication(1) in May 1954, on the first use of chlorpromazine in this country, we conducted a pilot study on 90 patients to determine optimum dosages and types of complications of this tranquilizing agent. With negligible ill effects established in this group, a hospital-wide study project was initiated January 1, 1955, and terminated June 30, 1956. The 23 physicians among 13 buildings of the hospital complex used dosages that were generally conservative throughout the 18 month period. During the first 6 months there was some restriction in the admission to treatment of categories of mental disease. Thereafter, the medical staff exercised free choice among all classified psychotics.

In addition to the clinical side-effects, the familiar complications of jaundice, leukopenia and agranulocytosis were well publicized and even over-emphasized to the staff. Winkelman had reported 5 cases of jaundice in 1,942 patients; in one state hospital, jaundice had occurred in 18 of 1,300 patients(2). The biochemical changes and histopathology of the liver in jaundice from chlorpromazine had been adequately described(3). It was known that 2 fatalities from liver toxicity had allegedly followed this new therapy(4).

This sobering intelligence ensured continued alertness of the staff to possible

hazards of chlorpromazine treatment even though some authors(5) felt strongly that the seriousness of side-effects and toxic complications were overrated. Throughout the program our physicians maintained cautious administration of the drug. Since a more objective evaluation of toxic complications was possible by laboratory studies, well over two-thirds of all cases had periodic liver function tests and hemograms performed.

MATERIAL AND METHODS

Case Selection and Laboratory Checks.—An extended range and number of acute and chronic mental diseases composed the institutional population. Among most of the chronic cases placed on chlorpromazine, there had been poor or short-lived response to single or combined courses of electroshock, insulin coma, sedation and lobotomy. Between January 1955 and June 1956, 3,014 patients were admitted to chlorpromazine therapy.² All age groups and both sexes were sampled—from boys and girls, aged 6 to 16—to senile patients as old as 81. The management of treatment crystallized into 3 distinct phases of 6 months each (Table 1).

Phase I was concerned with indoctrinating the staff in the pharmacology of chlor-

¹ Kings Park State Hospital, Kings Park, New York

promazine and searching for the most common toxic complications. Laboratory tests were done on nearly 200 patients in this group, chiefly when any clinical side-effects were noted. A battery of liver function tests and complete blood counts at weekly intervals were carried out on the 3 jaundiced patients and on all others on whom abnormal values of serum bilirubin or white blood cell counts were found.

Phase 2: There were 1,063 new cases in this second half-year period on whom therapeutic response, side-effects and toxic complications were documented. One-quarter of the 1,063 cases had pretreatment blood counts and serum bilirubin determinations. All cases, sometime during the first months of treatment, had these tests done on one or more occasions. Serum alkaline phosphatase determinations (Bodansky), cephalin flocculation and thymol turbidity tests were performed if an elevated bilirubin was discovered.

Phase 3: In this Determinate Group, each of the 1,215 new patients was subjected to a systematized procedure of clinical and pathological observation. Dosage, side-effects, therapeutic response and disposition of the patient were recorded. All patients were on the following laboratory regimen: (a) In the week before treatment, a complete blood count, total serum bilirubin and serum alkaline phosphatase. (b) These 3 tests were repeated between the 14th to 21st day of treatment and thereafter at 3 to 4 week intervals. Patients with abnormal values had these tests repeated weekly or oftener.

Dosage and Duration of Treatment.—The dosage, on the first day, was 25-50 mgm. of chlorpromazine intramuscularly; then 75 mgm. IM, plus 100-200 mgm. orally from the 2nd to 7th day for two-thirds of the 3,014 cases; the other third received 300-400 mgm. orally, from the beginning. As the physicians gained experience and lessened their apprehension of immediately unfavorable reactions, the intramuscular route was largely abandoned in the last 6 months, especially for senile patients who commonly required bed rest after this route. We found no clear cut clinical picture of skin hypersensitivity following the first dose. The real merit of these putative doses was

in the detection of transient hypotension necessitating temporary bed rest, chiefly during the first week of medication.

About 90% of all patients received average dosages between 300-400 mgm. daily from the 2nd week to the 2nd or 3rd month; most of the remainder got smaller amounts. As soon as the mental condition showed improvement, the dosage was gradually reduced to a maintenance level of 200 mgm. daily. This was continued until eligibility for discharge. During the first 6 months (Phase 1), 26 cases were treated with 500 to 1,000 mgm. daily but showed no appreciable therapeutic advantage. We saw no need for the large doses given by Kinross-Wright (5b). In his 251 cases, the daily dose averaged 1,400 mgms. with a maximum of 3,400 mgms.

Our courses ranged from 3 to 18 months except that 77 patients have, at this writing, received chlorpromazine several months beyond the 18 month period without complications.

Program Deficiencies.—Therapeutic response, side-effects and toxic complications among the 3,014 cases were admittedly studied in breadth without great depth. Serial laboratory checks were done at 2 to 4 weeks intervals which may not be frequent enough. The large number of cases and data so recorded may offset some statistical deficiencies that might have been avoided in more frequent observations. Pooling of the experiences of 23 physicians had the merit of integrating a wide range of attitudes to the effectiveness of chlorpromazine therapy.

Minor hepatic or leukopenic complications may have been overlooked in the early months of the project. Serious sequelae were not likely to be missed during daily ward rounds since continued medication would expectedly aggravate the ill effects. During Phase 1, serum bilirubin elevations between 1 and 2 mgms. occasioned temporary suspensions of medication that were not always recorded. As experience with these slight bilirubin elevations showed only a small likelihood of a further rise on continued medication, the interruptions were eliminated.

Even with occasional deviations from the prescribed schedule, over 21,000 laboratory

determinations were performed during 1955. (Phases 1 and 2), on 1,799 new cases—an average of over 11 tests per case. The particular tests were selected chiefly for interpretative consistency, technical simplicity, a minimum of venepunctures and suitability with small blood samples.

CLINICAL ASPECTS

Therapeutic Action.—Response to treatment during the 18 month period was adequately charted, in spite of intramural transfers, on 8 of the 13 psychiatric services in the program. The results among 1,534 cases treated from 3 to over 18 months are summarized in Table 2.

There are no universally accepted parameters for recording shades of improvement in mental disease. For this reason, only two states of therapeutic response are listed in Table 2. The first, "Fair," includes any noticeable change, for the better, in any of the mental symptoms in the field of behavior. The second, "Good," includes the first stage of behavioral improvement plus a decrease or removal of delusional or hallucinatory features characteristic of the mental diagnosis. Among the 8 services of Table 2,

therapeutic appraisal by the optimists and skeptics balanced out to merge with the judgments of those with more neutral approach.

The influence of chronicity of disease on the effectiveness of chlorpromazine was not generally calculated although one of us, (E.A.), in 247 highly disturbed chronic cases, found the average duration of illness was 10 years and 2 months. It was seen early that the drug follows the therapeutic *cliché* that the degree of improvement is inversely proportional to the duration of the disease.

The percentage of any degree of improvement by chlorpromazine is outlined in Table 2. This is slightly higher than in other reports, particularly that of Goldman on 506 cases(6)—first, because we recorded the mildest symptomatic changes and secondly, we usually treated for longer periods. One minor exception to prior reports is that we did not note frequent early disappearance of hallucinations. These largely persisted for some months although they were less apparent in the general suppression of untoward psychomotor activity. There were no actual "cures" in the absence of suitably

^a Good indicates both behavioral and ideational improvement with 10-20% suitability for discharge on convalescent care.
^b Fair indicates any degree of sustained improvement in behavior with little or no change in psychosis—not eligible for discharge.
^c Includes chronic brain syndromes such as cerebral arteriosclerosis, Huntington's Chorea, postencephalitic syndromes, traumatic psychoses, general paresis and a few psychoneuroses or psychopathic personalities.
^d Convulsive symptoms not markedly affected—anticonvulsant agent continued with chlorpromazine.
^e Includes melancholia and paranoid states.
^f One-third of these became worse in contrast to other psychoses with no adverse effect by the drug.

follow-up periods. On 3 chronic services of 597 cases, (12%), were discharged on convalescent status. On the 5 services, discharge rates ranged from 5% to 15% depending on the diagnosis and composition of case material.

The prominent effect of chlorpromazine, especially on patients hitherto not amenable to other forms of mental therapy, was on emotional symptoms. Response was usually evident within the first month, but often required over 3 months of medication. Moderation of the underlying psychosis was gradual and less constant, requiring at least 2 and commonly up to 6 months of continuous treatment to modify or eliminate delusional or persecutory ideas.

Chlorpromazine was found to be of minimal or uncertain effect in purely depressive states—involutional melancholia, catatonic stupor, severe social withdrawal, and the like. In a large minority of such psychoses there was an aggravation of symptoms, as also noted by Hoch and coworkers(7) in their 2-year study of 300 mental cases. The most satisfying responses were in agitated phases of dementia praecox, manic-depressive (manic), and alcoholic psychoses. In excited patients with mental deficiency or convulsive disorders, chlorpromazine was primarily a tranquilizer, only partly altering the fundamental disorder. This also applied to most of the organic psychoses listed under Miscellaneous in Table 2. On one continued-treatment service, 14 female epileptics on anticonvulsant medication had suffered a total of 64 seizures in the 6 months before chlorpromazine. During the first 6 months on the drug, there were only 36 seizures in the group. This reduction may be related to diminished susceptibility to environmental stimuli.

The consensus was that at least 3 months of sustained treatment was needed to judge the efficacy of chlorpromazine. The technique tried elsewhere of repeated 1 to 2 month courses of dosage was abandoned early because of common relapses within a few weeks after discontinuing the drug. Winkelman has rightly stated(8) that chlorpromazine medication is as sensitive and skilled a procedure as the use of insulin for the diabetic or digitalis for the cardiac.

Clinical Side-Effects.—Table 3 summarizes the pronounced side-effects among the 1,534 patients. Undesirable effects have been publicized but their frequency and weight vary with the observer and diagnostic categories. Among our hospitalized patients, subjective complaints during treatment were far less prominent than in office practice dealing with a large component of psychoneuroses and anxiety states. The latest study of side-effects has been by Cohen(9) on 1,400 inpatients. He divided complications into major and minor groups with the former, as we found, far less frequent. We do not consider, as he did, the commonly occurring somnolence to be a complication, but rather a part of the tranquilizing action. Table 3 excludes those undesirable effects which were ephemeral, or which caused no real distress. If one eliminates single episodes, lasting a few minutes or hours during months of treatment, the forms and frequency of side-effects are not impressive. We encountered no permanent sequelae in any case, even in well over 18 months of medication among 77 patients. Complications were of greater moment for the apprehensive physician than for the patients themselves.

Excluding jaundice and severe neutropenia, the side-effects in therapy of chlorpromazine should be regarded in the same tolerant light as those accompanying antihistaminic or atropine therapy. Aside from jaundice, these disturbances disappeared in a few days to a week, even if medication was not stopped. It is possible that our low incidence is related to the consistently mod-

erate doses employed, since such side-effects as apathy, blurring of vision, Parkinsonism or swelling of the female breasts have been associated with high dosages(9).

Only 6 of the 25 patients with tremors showed true Parkinsonism with typical facies, pill-rolling and changes in gait or speech. The multiform rashes occurring in the first 2 weeks do not include the occasional photosensitive reactions. Photosensitivity became increasingly rare as prophylactic measures were emphasized. Jaundice was present in 9 of 1,534 clinically documented cases as compared with 13 among the entire series of 3,014 patients. Fever, usually associated with tachycardia, occurred chiefly in the first few days of treatment and was usually below 101° by rectum. Convulsions occurring once or several times were noted in 17 patients although most reports do not include this side-effect.

A few physicians, more concerned with mental improvement, maintained treatment in the presence of many of the listed side-effects. It was a common experience that, excluding rash, jaundice, or a pronounced leukopenia, the other ill effects would almost always disappear in a few weeks while on medication either in the usual or reduced amounts.

LABORATORY ASPECTS

Blood counts were made in over half of all the cases in the week before beginning treatment. A like number of bilirubin controls was used to exclude preexisting liver diseases. The rationale of selection in the Determinate Phase 3 of only two liver function tests, the total serum bilirubin and the rapid serum alkaline phosphatase technique recently devised by Goldenberg(10), is presented elsewhere by Cares and Newman(11). The Goldenberg method for alkaline phosphatase requires only 0.1 ml. of serum; it is not affected by hemolysis and its few steps are completed in a half-hour. Its accuracy equals or exceeds currently used procedures.

Other hepatic function tests—cephalin flocculation, thymol turbidity, cholesterol-esters, etc., which were frequently performed in Phases 1 and 2, were found too equivocal

as has been previously noted(12). The bromsulphthalein test could not be used where toxic jaundice was a potential danger.

Doses and Liver Function in Jaundice.—There were 13 cases of toxic jaundice among the 3,014 patients on chlorpromazine therapy. The incidence of jaundice is lower than in the range from 1-3% usually encountered. Our figure of 0.43% is comparable to 0.62% of Cohen and Archer in 800 cases(13) and 0.2% of Goldman with 506 treated(6). Increased clinical alertness among our staff stemming from periodic laboratory checks, may have played a part in shortening or aborting the course of jaundice or other serious complications.

Table 4 summarizes the data of the 13 cases of jaundice during the 18 month program. (In the same period, 9 cases of obstructive jaundice from other causes were present in the hospital.) No jaundice was noted before the critical 2nd or 3rd week as has been evident in other studies(14, 4b). Case 8, with a mild jaundice for a few weeks, was discovered by serial bilirubin tests after 66 days of treatment. This late onset is not noted in other published reports.

Factors of age, sex and race were not significant among the 13 icteric cases. The dosage conformed to the average range except that Case 2 received only 1,300 mgm. in 26 days but had an elevated bilirubin for 350 days. In this patient, the drug had been continued through oversight for 8 days after the onset of jaundice. In contrast, Case 8 received over 26,000 mgm. before developing mild jaundice of short duration. The same case, on a second course of half the previous dosage, started 6 days after jaundice abated, showed normal liver function tests in the subsequent 2 months.

Toxic signs and symptoms associated with jaundice are outlined in Table 5. The subjective symptoms, as in most psychotics, were difficult to grade. They largely disappeared in a few days to a week after stopping medication.

Among the 1,215 cases in Determinate Phase 3, that had received serial liver function tests, there were 14 additional patients with mild elevation of serum bilirubin on treatment; 5 had values between 2 and 4 mgms/% and 9 cases between 1.25 and 2.

Weakness	5	7
Diarrhea	4	5
Fever	4	2
Malaise	3	3
Itching	2	4
Rash	2	2
Weight loss	2	5
Tremors	—	2

In the face of continued treatment, these values commonly fell below 1 mgm. in a few days or weeks, except in one case where the bilirubin stayed above 2 mgms. for 62 days; another with 2.5 mgm. found in the second week of therapy, dropped below 1 mgm. two days later. Among the pre-treatment controls there were 18 patients with bilirubin values between 1 and 1.5 who showed no rise during treatment.

A statistical evaluation of the collected serum bilirubin readings during Phase 3 among 1,215 patients, including 7 jaundiced cases, has been made by Cares and Newman(11). They found that the mean serum bilirubin values showed no significant difference from the control values. Viewed as a whole, the treated group experienced negligible rises of serum bilirubin during the first weeks and months.

Correlations of Jaundice.—(a) *Onset and Duration:* The onset is calculated in Table 4 from the first day of treatment. Case 1, icteric on the 11th day, remained so for 65 days. Case 2, with no jaundice until the 24th day, was icteric for almost a year. In case 8, with the latest onset, 66 days, jaundice lasted only 18 days. No consistent relationship could be found.

(b) *Total Dosage and Duration:* Case 2, with the lowest total dose, had jaundice for 350 days while in Case 8, receiving the greatest dose, icterus lasted 18 days. Case 7 received 4,250 mgms. and jaundice persisted for 120 days. No relation existed between the total dosage and the period of jaundice.

(c) *Intensity of Jaundice and Duration:*

Cases 2 and 7, with high bilirubin values, remained icteric considerably longer than Cases 4, 10 and 12 with medium or low values. This conforms with the course of icterus in non-chlorpromazine conditions.

(d) *Bilirubin and phosphatase tests:* All cases with jaundice showed elevated alkaline phosphatase roughly paralleling the rise of bilirubin. This is amplified below.

The jaundice caused by chlorpromazine is a highly individual feature of acceptably low incidence without desirable stigmata of predilection. Its mechanism is that of an intra-hepatic biliary obstruction (3c), reversible in nature. We agree with other workers(9, 15) that the jaundice is an expression of an unpredictable drug idiosyncrasy, comparable to the occasional reaction seen in the use of thiouracil, methyltestosterone and certain arsenicals.

Serum Alkaline Phosphatase.—It was evident quite early in the 18-month program that one effect of chlorpromazine was a frequent elevation of the serum alkaline phosphatase. This was intercurrently confirmed in late 1955 by Stacey and associates(14) who were impressed by hyperphosphatasemia occurring at or before the rise in bilirubin. In 7 of their 70 patients subjected to serial liver function tests, a rise in serum alkaline phosphatase was manifested between the 9th and 19th day of treatment. In contrast, a recent study of hepatic pathology in 4 cases of jaundice, showed normal alkaline phosphatase levels with high total bilirubin values(3c). Contrary to Goldenberg's(16) recommendations, we purposely did not stop treatment when phosphatase readings were high, provided the serum bilirubin stayed normal. This was done to ascertain the frequency of icterus associated with phosphatase rises, as seen in Table 6.

The normal values in this table for serum alkaline phosphatase are from those given by Goldenberg(16). However, normal values in our laboratory with this same procedure, ranged between 0.8 and 6.4 units with a mean of 3.1 on 469 pretreatment determinations. None of this screened group had any manifest liver or bone pathology.

The normal upper limit of serum alkaline phosphatase varies with the method and the

* Maximum reading in 2 to 8 determinations, each case. Normal range .9 to 3.9 units. On treatment, values to 5 are common. Above 5.5 units, treatment not recommended by Goldenberg.

particular laboratory.^a The Goldenberg procedure yields values corresponding to the Bodansky method. Bodansky phosphatase values of less than 7 units are considered to be of little clinical significance in the absence of other relevant findings. Table 6 indicates that the serum alkaline phosphatase may rise in some cases on chlorpromazine treatment.

In serial liver function tests, 7 of 70 cases treated by Stacey's group (14) had elevated serum alkaline phosphatase considered unrelated to a rise in serum bilirubin. In a statistical computation on our 1,215 cases, Cares and Newman (11) found a positive correlation of 0.51 (as opposed to $\pm .2$ or $\pm .3$ attributable to pure chance). This figure is too low to be of clinical value. Among the 72 cases listed in Table 6, with over 8 phosphatase units, 13 had jaundice, a frequency of less than 1 in 5.

The significance of elevated alkaline phosphatase as an indicator of impending jaundice from chlorpromazine is not pronounced. In Table 6, there is doubling of the frequency in the middle range, 5.5-8 units, over the control group. The rise usually occurred in the first 3 weeks on treatment. We had 2 cases with serum bilirubin values below 1 mgm. that had over 20 phosphatase units repeatedly during several months on treatment. Normal phosphatase readings (below 3.9) with a rise up to 3 mgms./% of bilirubin were encountered in 8 of the 14 subicteric cases discussed above. The weak relation existing between serum bilirubin and alkaline phosphatase, in our large series of tests, was of no help in predicting toxic jaundice.

^a Checked in Goldenberg's laboratory, our sera showed an average reading .2 unit lower than our own findings of alkaline phosphatase, a reasonable deviation between laboratories.

Leukopenia and Altered Hemograms.—Leukopenia and agranulocytosis have been reported in chlorpromazine therapy but quantitative changes are often not mentioned. Denber and Bird noted 2 cases, simply labeled as leukopenia, among 1,300 treated. Two recently reported deaths from agranulocytosis following 2 months of chlorpromazine administration (17), point up the need for repeated blood cell counts, certainly during the first 3 or 4 months. During Phase 2, no case with less than 4,000 leukocytes was present among 1,063 cases started on treatment. In Phase 3, 2 to 8 complete blood counts were done on the 1,215 patients and 2 cases of severe neutropenia and agranulopenia were found. Secondary anemia, stemming from the use of the drug did not occur in any of the 3,014 cases.

Our laboratory files were reviewed for the incidence of leukopenia and neutropenia on a control group in Phase 3. All definite blood dyscrasias or evident systemic disorders inducing depressed leukocyte values were excluded from this group, which consisted of 757 recent hospital admissions and 490 patients in the week before starting chlorpromazine, 1,247 in all. The comparative figures comprise Table 7.

Among the 1,247 controls, 11.5% had counts between 4,000 and 5,000 leukocytes/cu.mm. compared with 22.6% among the treated cases. Between 3,000 and 4,000 w.b.c., the percentage is respectively 1.4 and 2.5. The incidence of leukopenia present in the control group has been consistent in our hospital for the past 5 years, since 35% of admissions are over 60 years of age, in whom mild anemia and leukopenia are not infrequent. Among the 490 cases who had pretreatment blood counts, a good proportion

TABLE 7

had been hospitalized 6 or more months. Many of these reflected the mild malnutrition often seen in mental patients.

In Table 7, the incidence of leukopenia is roughly doubled during chlorpromazine treatment. Leukopenia, from 2,000 to 3,000 white blood cells per cu. mm., occurred during therapy in 4 patients. Counts below 2,000 cells, with marked neutropenia, developed in 2 of 1,215 treated cases. In the 18-months' study, one additional case of leukopenia with less than 2,000 cells was incidental to jaundice (Case 2—Table 4). Thus, pronounced leukopenia was seen in only 3 of 3,014 treated. The leukocyte count returned to normal within a month after stopping medication, following simple supportive therapy.

No instance of drug-induced leukocytic depression appeared after the third month. Serial leukocyte counts were considered essential in these first 3 or 4 months since the onset of leukopenia was insidious. Eosinophilia up to 6% was present in less than 25 cases and was commonly associated with skin rashes.

CONCLUSIONS

1. There were 3,014 cases admitted to treatment with chlorpromazine in doses of 200 to 400 mgm. daily during an 18-month period beginning January, 1955.

2. Response to treatment was best in agitated states of most mental disease categories. It was poorest in akinetic states with a good proportion showing a deepening of their depression. Side-effects were infrequent and not serious, appearing in the first 2 weeks and often subsiding on continued therapy. There were no permanent sequelae even after more than 18 months of medication.

3. Jaundice occurred in 13 patients, an incidence of .43%. No relation was found

between the jaundice and amount or duration of dosage.

4. Leukopenia below 2,000 white blood cells cu. mm. was found in 3 patients (.11%) all of whom recovered on withdrawal of treatment.

5. Serial tests for total serum bilirubin, serum alkaline phosphatase plus complete blood cell counts were done on 1,215 cases. These periodic checks may have helped in maintaining a low incidence of toxic complications by sustaining clinical alertness.

6. During chlorpromazine therapy, the serum alkaline phosphatase rose more frequently than did the total serum bilirubin. Only one-fifth of the cases with alkaline phosphatase values over 8 units were jaundiced, a weak positive correlation.

7. Serial serum bilirubin and leukocyte counts during the first 4 months are useful in detecting the onset of toxic jaundice and/or leukopenia.

ADDENDUM

Two months and 320 treated cases after the close of the above period of survey, the first fatality occurred. This was a fulminating agranulocytosis in the 7th week of treatment.

A.T., a white female aged 50, with a psychosis due to epilepsy, had been on dilantin therapy since 1941. Chlorpromazine, 300 mgm. daily, was added beginning August 17, 1956. The pretreatment blood count and serum bilirubin were normal. On the 35th day on chlorpromazine, the leukocytes were 5,700/cu.mm. with 64% neutrophils, serum bilirubin .25 mgm./% and serum alkaline phosphatase 7.25 units (Goldenberg). On October 8, the 53rd day of medication, she suddenly showed a fever of 104° with pharyngitis, submaxillary lymphadenitis and mild jaundice. A blood count revealed only 450 leukocytes with no granulocytes. The total serum bilirubin was 9 mgms., the phosphatase 7.44 units. With antibiotics and supportive therapy, there was some improvement in the last 2 days. A repeat blood count on October 11, 1956 disclosed 825 white

cells with no granulocytes. The patient died 12, 57 days after beginning chlorpromazine therapy. Autopsy findings confirmed the diagnosis of agranulocytosis.

As 443 new patients had been admitted to chlorpromazine therapy from July to September 1956, this is the only death implicating chlorpromazine among 3,457 patients treated from January 1, 1955.

The consistent cooperation of Dr. J. Hetherly Haight, Clinical Director, is gratefully acknowledged.

THE ANTIDOTAL ACTION OF SODIUM SUCCINATE IN THE MESCALINE PSYCHOSIS¹

IAN STEVENSON, M. D.,² AND ANDREW J. SANCHEZ, JR., M. D.³

The study of the experimental psychoses has already advanced our understanding of psychopathology. The exact relevance of the experimental psychoses to the problems of naturally occurring psychoses, such as schizophrenia, remains unclear. Nevertheless these two types of states have enough psychopathology in common to warrant much further research. The antidotes to the experimental psychoses deserve attention because of the understanding which they may give of the mode of action of the hallucinogenic drugs, and because of their possible eventual relevance to the biochemical treatment of natural psychoses.

Previous authors have described studies of several antidotes to the experimental psychoses. Thus nicotinic acid has some antidotal action in the lysergic acid diethylamide psychosis(1); chlorpromazine(2, 3) and sodium amytal(4) have some antidotal action in the mescaline psychosis; Frenkel has some antidotal action on both the lysergic acid diethylamide psychosis and the mescaline psychosis(5).

Quastel and Wheatley(6) demonstrated that the barbiturates and certain other narcotic amines, including mescaline, do not inhibit the oxidation of succinate as they do that of glucose, lactate and pyruvate. This led to the use of sodium succinate in antagonizing barbiturate anesthesia and poisoning in animals(7, 8, 9) and man (7, 10, 11). Schueler(12) repeated and confirmed the *in vitro* experiments of Quastel and Wheatley mentioned above. He then conducted four experiments on human subjects in whom he demonstrated a definite antidotal effect of sodium succinate on the symptoms of the

mescaline intoxication. We report in this article a series of experiments which have repeated and somewhat extended Schueler's observations.

METHOD

Subjects.—The 12 subjects were volunteers drawn from the staff of the department of psychiatry and neurology of the Louisiana State University School of Medicine and from the medical students of the School of Medicine. All were in good health physically and between the ages of 20 and 35. Ten were men and two were women.

Procedure.—Each subject was given 400 mgm. mescaline sulfate orally on two different days. The interval between experiments varied from a week to several months. Two observers studied the subjects and made notes of their behavior including verbal productions throughout the entire period of the effects of the drug until the effects were judged to have worn off sufficiently for the subjects to leave the experimental room and return home. This period usually varied from 8 to 10 hours, rarely longer. On one of the two experimental days each subject was given an injection of sodium succinate intravenously. A 30% solution (Brewer) was used. The dose of sodium succinate varied from 10 grams in one subject to 39 grams in another. Most subjects received 12 to 18 grams. The sodium succinate was administered slowly over periods of 30 to 90 minutes.

RESULTS

Effects of Mescaline.—The observed effects of mescaline on our subjects did not differ from those reported by other authors and are well enough known not to need repeating here. We shall add only that our subjects showed a wide variety of reactions to the mescaline, a fact to which little attention has so far been paid. Moreover, individual subjects showed different reactions on

¹ Aided in part by a grant from the Scottish Rite Committee on Research in Dementia Praecox, National Association for Mental Health.

³ Department of Psychiatry and Neurology, Louisiana State University School of Medicine, New Orleans, La.

different days. Our current work studies these differences further in a project combining psychological and biochemical techniques. We hope to clarify some of the factors responsible for the marked differences in reactions between different subjects. We mention this here because we observed an equally great diversity of response to the injection of sodium succinate.

Immediate Antidotal Action of Sodium Succinate.—We observed some antidotal action of sodium succinate in each of our subjects. However, the action varied rather widely and ranged from a slight antagonistic action to an almost complete erasure of the effects of the mescaline. The subjects themselves noticed the effects of the sodium succinate injections more rapidly and more markedly than the observers. They would often comment on the change spontaneously. Typical comments after receiving the sodium succinate were the following: "Things seem more normal. The colors are drab," "I feel like I am coming out of it. I feel definitely clearer," "Things seem much more real now. The walls don't move any more," "The color which was associated with the shapes left." The subjects noticed changes especially in their visual perceptions and in their moods. However, other aspects of the mescaline intoxication, such as ability to concentrate and "the sense of reality" were also affected by the succinate. The observers watching the subjects also noticed changes in their behavior, often within a few minutes after they received the succinate. They usually became much less expansive and less talkative. This effect merged with the fatigue induced by the sodium succinate (discussed further below), so that the subjects frequently became sleepy after the succinate injection.

Duration of the Antagonistic Effect of Sodium Succinate.—In some of the subjects the effects of the sodium succinate antagonism wore off within an hour or two and this led to a return of the mescaline effects. A second injection of sodium succinate repeated the earlier effect, but again, after another interval, the mescaline effects might return once more. Such relapses into the mescaline effects were always milder than the original experience before the sodium succinate, but

they were nevertheless quite definite. The following extracts from one protocol exemplify this sequence:

Subject J.B., white male, aged 24.

- 7:00 a.m.... Took 400 mgm. mescaline orally.
- 8:00 a.m.... Tense and slightly elated. Nausea.
- 8:30 a.m.... Disturbances of depth perception. Increased imagery. Color illusions.
- 9:30 a.m.... Mood elated; talkative. Marked disturbance of time sense.
- 10:30 a.m.... Disturbances of body image as well as of space and time perceptions. Feelings of unreality. Difficulty in thinking.
- 11:30 a.m.... Continuing with the same symptoms. Given 24.0 grams sodium succinate intravenously.
- 12:00 p.m.... Quieter; less talkative. Says he is not nearly as elated as he was an hour ago. Nausea and vomiting.
- 12:30 p.m.... Still some residual symptoms of perceptual distortions.
- 12:50 p.m.... Thinks he is about his normal self now.
- 2:00 p.m.... Symptoms have begun to return. Feelings of unreality have returned. Experiences himself as if in a dream. Perceptual distortions returning. Somewhat depressed in mood.
- 3:00 p.m.... Symptoms continue about the same.
- 4:30 p.m.... Persistent feelings of unreality. His speech somewhat unclear and his voice mumbles.
- 5:00 p.m.... Is withdrawn from others in the room. Does not want to answer questions. Having synesthesiae (seeing voices).
- 5:30 p.m.... Given a further 6.0 grams of sodium succinate intravenously.
- 5:50 p.m.... Greatly increased sense of reality. Sensations of warmth in body and some nausea.
- 6:00 p.m.... Seems recovered sufficiently to be taken home. However, on the way home preoccupied with minute details. Focuses attention on some small object for a long time. Talkative and seems to want much reassurance.
- 8:00 p.m.... Persistent feelings of unreality gradually wearing off again.

Figure 1 illustrates diagrammatically the antagonistic effect of the sodium succinate injections with the return of mescaline effects afterwards.

Total Duration of Mescaline Effects With and Without Sodium Succinate.—We attempted to estimate the end-point of the mescaline effects on days when the subjects

FIG. 1.—Diagrammatic representation of the course of mescaline intoxication with (dotted line) and without (unbroken line) the administration of sodium succinate. The figure illustrates the interference of the mescaline effects by the succinate, the return of the mescaline effects afterwards and the comparatively slight effect of the succinate on the total duration of the intoxication.

received sodium succinate and on days when they did not. This was easier to plan than to accomplish. The mescaline psychosis has no clear end-point. In our experience the psychosis evolves and declines approximately as follows. With oral administration there is a period of gradual onset lasting usually an hour to an hour and a half. There is then a period of maximal effects lasting an hour to an hour and a half. Following this the effects decline at first rather rapidly, but then much more slowly. This last period of some residual effects may last from 6 to 12 hours or longer. Several of our subjects noticed some (usually minor) effects for several days afterwards. One had a marked relapse after an interval of a day in which he was apparently normal. This gradual tapering of the effects makes impossible the assignment of a definite time for the end of the intoxication. It seemed easier to say when 80% of the effects had worn off than to say when they had worn off entirely; so we attempted to observe the time when the subjects, although not entirely normal, had largely emerged from the effects of the drug.

Having emphasized these limitations to our comparisons, we can present the following figures. As already mentioned, we con-

ducted 12 experiments without the administration of sodium succinate and 12 (on the same subjects) with its administration. The average duration of the effects (the end-point being taken when it was judged that 80% of the effects had gone) with the succinate was 9.1 hours and without the succinate was 9.8 hours. In 3 subjects the mescaline effects lasted longer with the succinate than without; in 2 subjects the effects lasted the same length of time with and without the succinate; in the remaining 7 subjects the effects lasted a shorter time with the succinate than without. These figures, and they must be considered approximate only, make clear that the succinate effect, definite as it was, did not appreciably shorten the total duration of the mescaline effects.

Incidental Effects of Succinate.—In addition to the antidotal effects of succinate we noticed other effects of this drug which have been described by other observers. The subjects sometimes complained of some pain in the arm of injection, especially if the injection was made rapidly which was usually not the case. They also exhibited marked flushing of the face and later of the neck and the extremities, especially the hands and feet. They usually felt warm, often sweated considerably, and were sometimes nauseated. (Mescaline also sometimes nauseated the subjects.) Respirations were usually increased and the subjects sometimes coughed and complained of an unpleasant salty taste. Almost invariably they experienced a strong sense of fatigue after the succinate injections. Again, mescaline alone frequently brought a sense of fatigue, but the succinate added greatly to this. The subjects often compared this symptom to their sensations after long walks, many sets of tennis, or heavy gardening. The combination of these symptoms frequently brought mild to moderate discomfort and sometimes some anxiety to the subjects.

Variations in the Antidotal Effect of Sodium Succinate.—As mentioned above, sodium succinate had some antidotal effects on each subject; the magnitude and duration of this effect varied considerably, as did the effects of the mescaline. The antidotal effect was not closely related to the size of the dose administered. For example, one of the most

marked antidotal effects occurred in a subject who was given 10 grams of sodium succinate. This amount in this subject produced a greater antidotal effect than that produced in the subject given the largest amount of succinate, 39 grams.

The variations in the antidotal effect of succinate did not appear correlated with the magnitude of the mescaline effect. Some subjects who were among those having the more marked effects from the mescaline did not show less response to the succinate than others who had milder effects from the mescaline. However, 2 subjects with marked effects from the mescaline stated that the injection of the succinate made their experience worse, that is, less pleasant. It seemed as if for these subjects the antidote only partially antagonized the mescaline effect. It deprived them of the mood elevating effect of the mescaline without entirely returning the perceptions and thought processes to normal. Other subjects found the side-effects of the succinate less pleasant than the euphoria which it interrupted. But although they felt worse after the succinate, we did not consider this a worsening of the mescaline intoxication. It was rather an incidental aspect of improvement.

Variations in the succinate effect were apparently not due to different rates of oxidizing and excreting the succinate. These variations were observed rather soon (*i.e.*, within 10 to 30 minutes) after the injection of the succinate and presumably before there had been time for much disposition of the succinate to have taken place.

DISCUSSION

The foregoing results confirm and add to Schueler's observation that sodium succinate has an antidotal effect on the mescaline psychosis. The mechanism of this effect remains unelucidated and is the object of further study in this department as is the wide diversity of responses both to mescaline and to succinate in different subjects. Two explanations which have been suggested to us to account for the effect of succinate we believe do not apply. The first is that the succinate acts as a stressor to the organism and in a sense "shocks" the patient out of his psy-

chosis. It is true that strong and even mild stimuli such as talking to the subjects tend to break up some of the symptoms of the mescaline effect. The subjects almost invariably report that they feel different and that "things seem more real and less dream-like" when someone is talking to them. And conversely, when they are left alone for a time or when they close their eyes, they tend to drift off into reveries if not actual dreams. It is also true that the succinate induces some associated unpleasant physical symptoms to which we have alluded above. However, we do not believe that these symptoms acting as stressful stimuli account for the antidotal effect. We observed an antidotal effect in subjects who experienced little of the kind of discomfort we have described. And in other subjects some of the antidotal effect was observed before the subjects experienced any significant discomfort. We have also considered a second suggestion that the antidotal effect of succinate derives from its alkalinizing action. We have attempted to test this hypothesis in studies to be reported later. In this place we shall say only that these studies fail to support this hypothesis.

At present, therefore, we believe the most plausible hypothesis of the antidotal action of succinate is that of Quastel and Wheatley and of Schueler. This is that the succinate provides a substrate for oxidation in brain tissues when the oxidation of glucose, lactate and pyruvate has been depressed by the mescaline. Further confirmation of this hypothesis will contribute to our knowledge of the mode of action of mescaline and allied drugs.

We have considered the relevance of these studies to schizophrenia. Osmond and Smythies proposed that the symptoms of schizophrenia are produced by the action of a substance similar to mescaline produced within the body during stress (13, 14). Such a substance could be a derivative of epinephrine or a by-product of its production. If such a substance acts through depressing oxidation in the central nervous system as mescaline appears to do, then succinate might be expected to antagonize it. Succinate has already been used in a small number of cases of mental disorder (15, 16) and beneficial effects reported. We plan to expand the

present studies to include observations of the effects of succinate on various patients of the group of schizophrenias.

SUMMARY AND CONCLUSIONS

1. Sodium succinate was found to have a definite antidotal effect on the mescaline psychosis in each of 12 subjects.

2. The effect varied greatly in different subjects. Moreover, the effect was rather transient and there was little shortening of the total duration of mescaline effect.

3. The most plausible hypothesis of the succinate effect is that succinate provides a substrate for oxidation in the brain tissues when the oxidation of other substrates, *e.g.*, glucose, lactate and pyruvate has been depressed by the mescaline.

THE PLACE OF RESERPINE IN THE TREATMENT OF THE CHRONIC PSYCHOTIC PATIENT

CHARLES P. GORE, M.D.,¹ GEORGE P. EGAN, M.D., AND
DONALD WALTON, B.A.

In the past few years a stream of reports concerning the use of reserpine in psychiatry has appeared. Remarkably favourable claims for its ameliorative effect on the behaviour of grossly disturbed psychotic patients have been made, and astonishing successes described. Although our study covers much well traversed ground we are publishing our results because they are at variance with, and much more conservative than, the findings of many similar studies. This report is divided into Part I, a controlled study and Part II, an uncontrolled study.

PART I

CLINICAL MATERIAL

The material was made up of 20 female patients suffering from chronic and intractable schizophrenia who were selected not on diagnostic grounds but because they were regarded by the nursing staff, who largely made the selection, as presenting exceptionally difficult nursing problems. Fifteen showed behaviour characterized by restlessness, overactivity, noisiness, and a tendency to strike out if carelessly or tactlessly handled. The other five were predominantly withdrawn, self-absorbed, difficult if not impossible to occupy, and required supervision with feeding and dressing. Five patients were incontinent, 2 persistently, 3 occasionally. Their age range was from 31 to 62 years with a mean of 45.9 years. Their duration of hospitalisation ranged from 2 to 29 years with a mean of 13.4 years.

Independently of, and prior to this trial 10 patients, because of their grossly disturbed behaviour, had been recommended for leucotomy by a majority of the clinical staff of the hospital. Eleven were on regular heavy sedation, mainly barbiturates, throughout the day, the others as dictated by changes in their behavior. Eleven had received either

electroshock or insulin coma therapy, at some time during their stay in hospital, without improvement.

METHOD OF INVESTIGATION

Before entering the trial all sedation was withdrawn. For an initial period of 4 weeks each patient was studied in order to establish a base line for her behaviour, blood pressure, pulse rate, and weight, and to note any variation which might otherwise have been attributed to the drug. Then a placebo, indistinguishable by patients and staff from reserpine, was given to 10 of the patients, the active preparation, reserpine, being administered to the other 10. After 3 weeks, placebo and drug were alternated, and this substitution was maintained for 3 weeks. Therefore, each patient acted as her own control, and at any one given time, half the patients were receiving the inert tablets, the other half the active preparation.

At the time the trial was undertaken there was no indication in the literature as to the effective dosage of the drug. Dosage was therefore, a matter of trial and error. Administration was begun with 1 mgm. b.d., this was increased to 1 mgm. t.i.d. after a week and for the third and final week, 1 mgm. q.i.d. was given. In 2 patients, this dosage led to marked cardiovascular changes, and could not be maintained. Tablets were prescribed according to the hospital record number, only one of us (C.G.) and the hospital pharmacist knew whether a patient was on the active or inert preparation.

Three times a week the mental state of each patient was systematically assessed by one of us (G.P.E.) by ordinary clinical methods combined with the use of a modified version of the Worcester Rating Scale (4). The day nursing staff made daily notes, and in addition rated each patient on an adapted version of the Johns Hopkins Hospital Behaviour Chart (6). The night staff noted the hours of sleep, and any dis-

¹ Menston Hospital, Nr. Leeds, Yorkshire, England

turbed behaviour at night. All information thus obtained was taken into account in determining whether any change had occurred in the patient's mental state. Weights were recorded weekly, the blood pressure thrice weekly, the pulse rate morning and evening.

FINDINGS

Mental.—Patients who had their customary sedation withdrawn showed a shortlived temporary exacerbation of symptoms following which they reverted to their former patterns of behaviour. During the initial period of observation it appeared in a general way that all were slightly better. This slight improvement was attributed to the increased interest taken by the nursing and medical staff in the patients.

In 16 patients no change due to the drug was observed. Four showed slight but definite improvement. This was attributed to the drug as it did not occur during the preliminary period of observation, nor when the placebo was exhibited, also the change was not maintained subsequent to the withdrawal of the drug, nor following the substitution of the drug by placebo. No patient improved whilst on placebo. The change in 3 patients was a damping down of their former restless, overactive and noisy behaviour. One patient who had previously been mute, and whose only activity was to continually tear her clothing and pull her hair out, ceased to indulge in these activities, become responsive, replied to questions, made spontaneous conversation and took an increased interest in her surroundings. No fundamental change in the basic illness occurred, improvement being entirely symptomatic.

Physical.—Weight: Despite improved appetite as indicated by increased food consumption, no significant changes in weight occurred. Those which were recorded could be attributed to chance variation, and not necessarily to the influence of reserpine. It is possible that the absence of significant weight change may, in part at least, be a function of the short time interval covered by this investigation.

Cardiovascular: The cardiovascular changes are summarised in Tables 1 and 2. The patients have been divided into two

TABLE 1

GROUP A MEAN AGE: 49.9

	No drug	Reserpine	Placebo	Degree of significance
Mean systolic . .	139.8	117.1	111.8	F. ratio 3.29*
Mean diastolic . .	90.6	75.3	75.6	F. ratio 2.18 not significant
Mean plus rate . .	76.7	64.9	68.1	F. ratio 23.10†

* Significant approx. .05 level of confidence.

† Significant beyond .01 level of confidence.

groups, A and B, depending on whether they received first the inert or active preparation.

The systolic changes: There is a tendency for reserpine to reduce the systolic pressures in both groups. Both groups show changes in the same direction and both are almost at the same level of significance. The effect of reserpine is significantly greater than the effect of the placebo, the value of *t*, the critical ratio, being 6.5, significant beyond the 0.01 level of confidence. The rank correlation between initial systolic level and the size of the subsequent drop under reserpine is significant beyond the .01 level of confidence (+.77). Those in this sample with the largest systolic blood pressure, tend to show the largest falls.

Diastolic changes: Group A with the higher mean diastolic pressure, does not show any significant change under reserpine. Group B, with a lower group mean diastolic shows a very significant drop. A statistical explanation of this difference can be gained from an examination of the size of the mean diastolic pressures of the two groups. Whilst there is approximately a 15 points drop for groups A and B, a drop of 15 in Group B

TABLE 2

GROUP B MEAN AGE: 41.9

	No drug	Placebo	Reserpine	Degree of significance
Mean systolic . .	111.3	105.3	92.3	F. ratio 3.02*
Mean diastolic . .	76.2	73.1	60.6	F. ratio 6.80†
Mean plus rate . .	77.3	77.9	70.9	F. ratio 7.45†

* Significant approx. .05 level of confidence.

† Significant beyond .01 level of confidence.

is proportionately greater than a drop of 15 in Group A.

One possible physiological explanation of these changes can be postulated from the two rank correlations calculated:

(a) Between diastolic level and subsequent drop.

(b) Between the size of diastolic drop and age of the subject. They were +.29 and +.37 respectively. Neither is significant. It is suggested that the older subjects showing the largest diastolic pressures (Group A, mean ages: 49.9, Group B, mean age: 41.9) are less likely to show any significant reduction, whilst the younger subjects with less functional resistance and lower diastolics, are more likely to do so. In the older age groups one is, therefore, perhaps less able to predict with accuracy that a fall in diastolic pressure will take place after exhibition of reserpine. In the younger group, with these chance factors minimised, prediction would appear more accurate and certain.

The value of *t* calculated for the significance of the difference of the changes effected by reserpine and placebo is 5.6. This is significant beyond the .01 level of confidence and shows that the reduction in diastolic pressure by reserpine is significantly greater than that effected by suggestibility, increased medical care, etc. during the administration of the placebo.

Pulse Changes: In Groups A and B the pulse rate dropped very significantly. There can be little doubt that this is attributable to the direct effect of the drug. In Group A when reserpine was withdrawn and the placebo given in its place, the pulse rate rose from a group mean of 64.9 to 68.1. Similarly in Group B, under the effect of the placebo the mean pulse rate remained approximately constant at the "no drug" level. After the introduction of reserpine the mean pulse rate fell from 77.9 to 70.9.

Incontinence: No change.

Side-Effects: Sudden and alarming bradycardia was observed in one patient. This was noted on the fourth morning of the trial, by which time she had received 6 mgms. of reserpine. Her pulse rate, which had constantly centred around the 70 mark fell to 38. At this stage she looked pale and ill. An attack of generalised bodily tremor last-

ing about 10 minutes was observed by the nursing staff. She stated that she felt sick and that she was too ill to shout or move about. Prior to this her behaviour was described as overactive, restless and noisy. She would spend most of the day shouting out of windows about atomic rays. The dose of reserpine was reduced to $\frac{1}{2}$ mgm. b.d. and it was not found possible subsequently to exceed $\frac{1}{2}$ mgm. t.d.s. without marked bradycardia. As soon as her pulse rate reached 50, there was a return to her very disturbed behaviour.

In another patient, it was not found possible to exceed a dose of 1 mgm. t.d.s. without causing a similar bradycardia. A physically healthy 32-year-old man (not included in this series), suffering from a crippling obsessional illness associated with considerable tension, developed a marked bradycardia—pulse rate 40, and a fall in blood pressure from 110/70 to 50/40, on a dose of 4 mgms. daily. He described a marked diminution of tension, this because he felt drained of all energy. Like the patient in this series, he looked pale and ill.

Drowsiness was observed in 6 patients. This was noticed on the third or fourth day. It was never troublesome, and passed off in 2 or 3 days without a reduction in the dosage of the drug.

No other side effects were recorded. This does not mean they did not occur but may merely be a reflection of the failure of such patients to report departure from their customary feeling state.

PART II

MATERIAL AND METHOD

This part of the study covers all cases at the hospital (43) treated with reserpine. Of these 9 had to be excluded because of inadequate dosage or too short a period of treatment. The remaining 34 (13 female, 21 male) had been diagnosed as suffering from schizophrenia, and were regarded as incurable. They had been selected on the grounds of the chronicity and intractability of their illness, and also because of their tendency to be a greater nursing problem than other patients either by virtue of overactivity or withdrawal. Their age range was from 22

to 67 years with a mean of 40.6 years. Their duration of hospitalisation ranged from 1 to 37 years with a mean of 9.4 years.

Twenty-seven had previously been treated with electroshock and/or insulin coma therapy, 8 had been subjected to prefrontal leucotomy, and most had been and were still on large doses of barbiturates. Some had received more than one form of physical treatment *e.g.*, ECT, and PFL.

The average daily dose of reserpine was from 3 to 6 mgms. and all cases had been treated for at least 12 weeks, 15 for more than 6 months. The response to the drug was estimated on the basis of 1. Interview with the patient; 2. Discussion with the doctor and nurse caring for the patient; 3. The progress notes recorded in the patient's file.

FINDINGS

Twenty-one patients showed no change. Four were regarded as slightly worse. In general they were considered to be lazier, more lethargic and dirtier, less concerned about their personal appearance, or somewhat noisier. One patient was assessed as much improved. This indicated a major change in behaviour permitting him to be on ground parole and to go home at weekends. Whether this can be wholly ascribed to the drug is doubtful since a review of his record showed that similar improvements had spontaneously occurred in the past. Eight patients were slightly improved. These patients were described as being less restless, more composed, tidier and more consistent at their work tasks. None had undergone a major change. In all cases improvement was entirely symptomatic, and there was no modification of the basic illness.

There was no correlation between improvement, dosage and duration of treatment. Improvement tended to occur within the first 3 weeks and to be maintained. A turbulent phase was not observed.

DISCUSSION

It is worthwhile emphasising that the withdrawal of sedation, although given in large doses, and over long periods to control disturbed behaviour, led only to temporary

short-lived exacerbation of symptoms. It is our impression that patients from whom barbiturate drugs were withdrawn showed slight improvement when free from the toxic effect of these drugs. When sedative drugs have been prescribed for whatever reason, there seems to be a tendency at least in mental hospitals, for successive doctors automatically to repeat the prescription. Our experience indicates that such use of sedatives is to be deprecated, and that they are no substitute for good nursing and medical care.

Only 13 patients (4 in Part I, 9 in Part II) showed improvement. This somewhat disappointing result may indicate that reserpine is only of very limited value in the treatment of chronic psychotic reactions, and since the improvement was entirely symptomatic it seems reasonable to conclude that the drug has no effect on the disease process itself, and that its only action is to lessen the intensity of symptoms. Furthermore it is difficult to decide if the symptoms which it improves are due to the disease *per se*. It seems to us that its main effect is on the symptoms which arise as a direct result of the conditions which are imposed on psychotic patients, *i.e.*, overcrowded and locked wards. Disturbed patterns of behaviour would, we suggest, undoubtedly occur in 'normal' people under similar conditions. In short, we are not convinced that reserpine or any other drug currently available can take the place of an enlightened approach to the care of these patients. As our findings are much more conservative than the majority of reports published particularly in America (7, 8, 3), it could be argued that the relatively poor results obtained in this study were a function of the methods employed. We do not believe this can be sustained. Since marked physiological changes occurred in the patients in Part I we conclude that dosages of 3-6 mgms. are sufficient for the drug to produce its effect, and that consequently higher doses are not justified. Furthermore the exhibition of the drug for periods of 12 weeks and more as in Part II is adequate to allow the physiological changes induced by the drug to reach a maximum. If the patient is not showing an improvement after 12 weeks the drug should be withdrawn.

The difference between results obtained in

America and our findings may possibly be a reflection of a differing approach to the care of chronic psychotic patients. Mental hospitals in this country are smaller, and whilst locked and overcrowded wards exist, "maximum security" wards are unknown, and there is a growing tendency to abolish all locked wards. This has been successfully done in some British mental hospitals. Bell (1) has shown that the unlocking of wards produces results as gratifying and dramatic as those attributed to reserpine (7, 8, 3). This tends to confirm our impression that reserpine's greatest effect is on the symptoms which are the result of environmental conditions imposed on the patients. Sergeant (10) is of the opinion that fewer reports of good results from chlorpromazine and reserpine are to be expected in Great Britain than in the U.S.A. and France, because of a putative higher standard of care in Great Britain. Clearly this is impossible to confirm as the necessary information is beyond our knowledge.

On the basis of our findings it seems to us that reserpine is in no way curative, and has only a limited role to play in psychiatry. Nor should it be overlooked that it is a dangerous drug and may cause depression of suicidal intensity (4), and even cardiac failure due to water retention though given in small doses (5). The sequence of events following the introduction of a new drug is well described in the *British Medical Journal* (2). The initial flood of favourable reports dries up and becomes replaced by those of another kind, and what was once a cure-all ends either by falling into disrepute or being regarded as only of limited value. Excessive claims for the efficiency of new drugs whether made by manufacturers or physicians are to be deprecated. It is obviously undesirable for manufacturers to release drugs for general use until they have been subjected to adequate clinical trial preferably by some competent medical research organisation.

The cardiovascular changes (Part I) are of considerable interest. The main points emerging from the findings are the higher

the systolic and the lower the diastolic pressure, the greater the fall attributable to reserpine. This suggests the effect of the drug would be greatest in cases of hypertension in which the rise in systolic pressure is proportionally greater than the rise in diastolic pressure. In well established cases of hypertension with a persistently raised diastolic pressure it seems probable that a reduction in the systolic pressure alone would occur, and the diastolic pressure would remain unaltered.

Cases of choice for treatment with reserpine should on our findings prove to be the early borderline, or "prehypertensive" ones. The findings summarised in Table II indicate that reserpine continues to exert its hypotensive effect for some weeks after its withdrawal. Bradycardia occurred in all patients, and was moderate except in the 2 cases referred to earlier.

SUMMARY

The effect of reserpine on the behaviour of chronic psychotic patients has been investigated by means of a controlled, and an uncontrolled study. The results indicate that it is only of limited value in the treatment of such patients. The extremely favourable results obtained by other workers were not confirmed.

CHRONIC PSYCHOSIS FOLLOWING EPILEPSY¹

J. E. A. BARTLET, M.D.²

INTRODUCTION

The relationship of the chronic psychosis to epilepsy is a controversial subject. Such questions as "Is there a true chronic epileptic psychosis?" "Can epilepsy and schizophrenia or epilepsy and an affective psychosis co-exist?" and if so "How do they affect each other?" and "What is the relationship between epilepsy localised to or commencing in the temporal lobe and the functional psychoses?" are still unanswered. This is what I have attempted to do from the highly selected group of patients attending the Bethlem Royal and Maudsley Hospitals. The results are necessarily tentative, but I consider of sufficient interest to warrant fuller investigation in a larger and less highly selected group of patients.

REVIEW OF LITERATURE

Kraepelin(1) believed that there was a specific form of dementia which was the result of epilepsy and had to be differentiated from dementia praecox. Vorkastner(2) believed that there was a condition of mental deterioration following on epilepsy which sometimes took on a dementia praecox-like colouring. Krapf(3) considered that true schizophrenia does not occur in epileptics, epilepsy does not complicate schizophrenia, but schizophrenia-like symptoms may follow epilepsy. Glaus(4) was of the opinion that true schizophrenia and epilepsy could occur in the same patient as independent conditions. Gruhle(5) considered that cases occur where what appears to be schizophrenia is interwoven with epilepsy and leaves it open as to whether one postulates schizophrenia with secondary symptomatic epilepsy, or idiopathic epilepsy with secondary symptomatic schizophrenia, or an accidental combination of both complaints. He finds no phenomenological difference between the form of primary delusions in schizophrenia and epilepsy.

More recently Alström(6), in his study of 807 unselected patients suffering from epilepsy at the Neurological Clinic of the Caroline Institute at the Serafimer Hospital, found 19 to be suffering from psychosis. They were diagnosed as follows: schizophrenia 7, dementia senilis 6, arteriosclerosis cerebri with psychosis 2, encephalitis lethargica 1 and alcoholic dementia 3. The author considers that this corresponds to what might be expected from a random sample of equal size taken from the general population. This is an important conclusion but loses value when it is remembered that all the cases attended a neurological clinic and were thus automatically a group with a disproportionately slight amount of mental illness. The patients with greater psychiatric disability would be more likely to come under the care of a psychiatrist.

Jones(7) in a comprehensive review of the literature concerning intellectual level, deterioration, specific disabilities and personality in epilepsy comes to the conclusion that there is no satisfactory evidence to support the view that epilepsy *per se* is responsible for intellectual deterioration, nor does he find validation for the classical concept of "the epileptic personality."

Hoch(8) dealing with the relationship between schizophrenia and epilepsy comes to the conclusion that they are two disorders which are not genetically related. His argument, based largely on the work of Conrad in epilepsy and Kallmann in schizophrenia, is as follows:

He takes the general average frequency of epilepsy as between 0.2 and 0.5% and that of schizophrenia as 0.85%. Hence he considers, before one may assume a genetic relationship between the two, there should be (a) an increase in the frequency of epilepsy in the blood relations of schizophrenics and the increase should be proportionate to the degree of consanguinity and (b) a similar increase in the frequency of schizophrenia among blood relations of epileptics. He finds neither condition fulfilled. He finds strong support for his hypothesis

¹ From the Bethlem Royal and Maudsley Hospitals, London, England.

² Consultant Psychiatrist, Park Prewett Hospital, Basingstoke, Hants, England.

ocular twin studies. He quotes Conners of 66.6% concordance rate in twins, (86.3% if restricted to idiopathic epilepsy) and Kallmann's figure of 81.7% concordance rate in schizophrenics, and concludes that no case of epilepsy in the monozygotic co-twin of a schizophrenic nor a case of schizophrenia in the homozygous twin of an epileptic has been reported. It appears from these results that patients with both epilepsy and a schizophrenic illness are so infrequent as not to alter the statistics significantly or that the diagnosis of epilepsy and schizophrenia have been regarded as being mutually exclusive. Of course if one subscribes to Krapf's view, epilepsy does not occur as a complication of schizophrenia but this is not the view held by such authorities as Kalilbaum(9) and Kraepelin(1) and more recently Esser cited by Kalinowsky and Hoch(10).

There is a rapidly enlarging literature on the subject of the relationship between temporal lobe lesions with or without epilepsy and psychiatric disorder. Gibbs(11) reviewing 458 cases with EEG evidence of focal seizure discharge found the anterior temporal region the most vulnerable area of the cortex and that psychiatric disorder was more than three times commoner in cases with focal seizure activity in the temporal lobe than any other cortical area. He found such cases clinically indistinguishable from "purely psychiatric" disorders. He considers that the ictal or psychomotor phenomena accompanied by focal EEG abnormal activity and the non ictal psychiatric abnormalities although not temporally related, are anatomically associated.

Mulder and Daly(12) discuss 100 outpatients who had lesions of the temporal lobe and whose presenting complaints were usually thought to be psychiatric. The lesions were localised on the basis of a complete examination and included 24 tumours in the temporal lobe of the cerebrum, 23 atrophies of the temporal lobe and 53 lesions of the temporal lobe in which the underlying pathological process was obscure. A focus of abnormal electrical activity in one temporal lobe was found in 65 patients. Abnormal electrical activity in both temporal lobes was observed in 10 patients. Diffusely abnormal EEG tracings were seen in 7 patients. Six-

teen patients had normal records. They divide their patients into 2 groups, those with paroxysmal and those with non-paroxysmal symptoms. The latter consisted of 62 patients and are subdivided by the authors into 36 anxiety states, 16 reactive depressions and 20 schizoid disorders. They found only 2 of the schizoid group psychotic and of the whole series only 4 psychotic.

Hill(13), discussing surgery of temporal lobe epilepsy referring to the same clinical material but not with the same selective criteria as myself, is in agreement with Mulder and Daly, and Gibbs regarding the relationship between temporal lobe lesions and psychiatric disorders. He considers there is a greater incidence of personality disorders in those patients in whom the focus is placed posteriorly in the temporal lobe rather than towards the temporal pole. He also quotes Liddell's, at the time of his paper, unpublished work at Runwell Hospital. A temporal lobe EEG focus was found in 50% of his epileptic patients which comprise 4.3% of the hospital population. In 78% of those with temporal lobe foci behavioural automatisms occurred. Hill compares these figures with those given by Jasper, *et al.* (14), for the general epileptic population about 1 in 5 of whom are believed to have temporal lobe origin for their fits. He noted that out of 13 cases of epilepsy with psychosis personally observed, 11 demonstrated a temporal lobe origin for the seizures. Karagulla and Robertson(15) point out the similarity between some of the subjective experiences of temporal lobe epilepsy, spontaneous or electrically induced in patients subject to temporal lobe epilepsy and some schizophrenic symptoms.

Thus in my sampling of the literature on the subject of psychosis and epilepsy we have 5 approaches.

1. The Continental psychiatrists in the tradition of Kraepelin describe a series of cases in which they find features that look like epilepsy and schizophrenia and manipulate the facts in an attempt to fit them into their hypothesis that schizophrenia and epilepsy are disease entities with a specific organic basis.

2. The neurologist investigates statistically the patients attending his clinic and

finds no evidence that epilepsy predisposes to psychosis.

3. The psychologist finds no evidence of epilepsy causing intellectual impairment nor of a specific "epileptic personality."

4. The geneticist finds schizophrenia (and for that matter manic-depressive psychosis) and epilepsy unrelated conditions.

5. Workers with a clinical neurophysiological approach to the problem particularly with an emphasis on EEG studies find evidence to support the hypothesis that paroxysmal temporal lobe dysfunction is related to non-ictal psychiatric disorder.

Meduna's(16) hypothesis that schizophrenia and epilepsy were mutually incompatible conditions does not seem to be standing the test of time, but there appears to be little doubt that psychotic illnesses where there is a large affective element benefit from artificially induced convulsions(17, 10).

THE STUDY

Scope: The case records of all patients with a diagnosis of psychosis following on epilepsy and with the combined diagnoses of epilepsy and psychosis attending the Bethlem Royal Hospital and the Maudsley Hospital between January 1, 1949 and December 31, 1953 have been studied and the cases which satisfy the following criteria selected.

1. The epilepsy antedated the onset of the psychosis.

2. The patient continued to suffer from delusions for a period of at least one year.

This selection was decided upon to exclude (a) any patients with schizophrenia complicated by epileptic seizures and (b) the group of epileptic patients who develop an acute psychosis, typically with disorientation, delusions and hallucinations, which does not become chronic. Glaus(4) and Hill(18) have discussed the former and Cobb(19), Gibbs(11), Mulder and Daly(12) and Hill(13) the latter group.

Definitions and Criteria: For this investigation epilepsy is defined as a sudden alteration in, or loss of, consciousness accompanied by an abnormal paroxysmal discharge of the cortical grey matter. The essential criteria have been clinical; that is, an account by a reliable witness as well as the patient's own account. Electroencephalographic evidence was always present to support the diagnosis.

Clinical and EEG evidence was also used in postulating the commencement of the discharge in a local area of the cerebral cortex.

The psychosis with delusions, in all cases was considered to be of sufficient severity to have caused the patient to come to a psychiatrist irrespective of the epilepsy.

The classification has been as follows:

I. The cases that would have been diagnosed as schizophrenia (mostly "paranoid" due to the prominence of delusions) if no evidence of epilepsy had been present. In this I follow Eugen Bleuler(20) stressing particularly the first two of his fundamental symptoms, i.e., disturbance of affect, particularly incongruity, or perhaps more usefully, inconsistency; (I introduce the idea of "inconsistency" rather than "incongruity" to overcome the difficulty that in a schizophrenic patient there may be undetectable congruity of mood and thought) and disturbance of thought, particularly of association. I also include Goldstein's(21) and Benjamin's(22) criteria of loss of conceptual thought as detected for example on asking the patient to give the meaning of a series of proverbs. Bleuler's third fundamental symptom of predilection for fantasy against reality or "autism" did not prove a useful concept. If delusions and possibly hallucinations were present along with the former 2 symptoms, a subjective evaluation of the patient's preference for reality or fantasy seemed to add nothing further to my assessment, nor was it found valuable in distinguishing such cases from the following group.

II. Cases of gradual onset arising out of an abnormal personality with delusions centered round relatively few primary false beliefs and with some degree of systematisation. Apart from these delusions the patient's thought processes were little disturbed and he was in a relatively normal relationship with his environment. Any disturbance of affect was considered to be secondary to the incapacitating nature of the illness or to the content of the delusions. These I call paranoid reactions.

III. Cases that would have been diagnosed as affective psychoses if no evidence of epilepsy had been present. In these cases there was a marked disturbance of mood, and delusions which were congruous with the dis-

turbance of mood. In this group there was no evidence of inconsistency or incongruity, in Bleuler's sense, of affect, nor involvement of conceptual or associative thought processes.

IV. Cases with unequivocal intellectual impairment, *i.e.*, dementia.

Results: Twelve cases satisfied my original criteria (see appendix). Ten have been examined by me. The eleventh, Case 6, at present in a mental hospital, has been reported on by the physician superintendent. The twelfth, Case 5, could not be traced but was adequately documented, and is included. If the epilepsy were ignored they could be fitted into the following diagnostic categories, by the standards laid down above.

I. Schizophrenics	8
II. Paranoid reactions	0
III. Affective psychosis	3
IV. Dementia	1

DISCUSSION

Eight of the above cases developed a clinical picture that in my opinion if epilepsy had not been present most psychiatrists would have called schizophrenic. In one, case 8, there might have been some difference of opinion as to whether or not he was suffering from a paranoid reaction. At present he does seem to be settling down to a well circumscribed paranoid system, centering round one delusional idea, but I feel it is legitimate to classify it as paranoid schizophrenia. The picture in 3 was predominately affective. One, case 9, was that of a depressive psychosis in a mentally backward patient. The other 2 cases, 10 and 11 are classified as hypomania. They have the features in common that the onset appears to have been in the form of a divine revelation and the delusions and affective abnormality appears to be related to this and a fixed idea that the patient has a mission. The remaining case, 12, is that of an undiagnosed dementing organic state with epilepsy antedating the clinical deterioration.

The population from which the above cases arise is made up as follows: 3,557 admissions (these figures exclude readmissions apart from the period 1.8.1953-31.12.1953), 12,015 outpatients (a number of outpatients subsequently became inpatients).

The number of patients suffering from

epilepsy was considered to be approximately 1,073 for the following reasons: for the period 1949-51 from the records department 223 had been diagnosed epilepsy. The number of patients attending the hospital has been steadily increasing so the figure arrived at by multiplying by 5/3 for correction from the period 1949-51 to the period 1949-53 is almost certainly lower than the correct one. This gives a figure of 373. Approximately 700 patients suffering from epilepsy are still attending the hospital several years after first attendance and are not included in the figures reaching the records department as their cases have not been "closed." (This source of error is excluded in my case material as I was working in the clinic for the epileptics of the hospital for the period 1.4.1953-31.1.1954 and any suitable cases are included.)

It is, therefore, considered justifiable to say that the 8 schizophrenic-like psychoses, 3 affective psychoses and 1 dementia with delusions occurred in a population of approximately 1,073 epileptic patients referred to the hospital.

Thus the incidence of schizophrenic-like conditions by my original criteria has an occurrence rate of approximately 0.75% in the epileptic population of this hospital. Hence I consider there is no evidence to suggest that chronic schizophrenic-like conditions occur more frequently in epileptics in the group investigated than schizophrenics in the general population (taking for example Kallmann's figure of 0.85%).

For the period 1949-53 the patients admitted to the hospital with a schizophrenic or affective illness (without epilepsy) of over 1 year's duration were given diagnoses as follows:

Schizophrenic disorders (dementia praecox) ..	167
Simple type	21
Hebephrenic type	27
Catatonic type	7
Paranoid type	76
Acute schizophrenic reaction	1
Latent schizophrenia	3
Schizo-affective psychosis	14
Other and unspecified	18
Manic-depressive reaction ..	121
Manic and circular	17
Depressive	95
Other	9

(These figures were obtained from the records department.)

Using this diagnostic scheme my 8 schizophrenic-like conditions would have been diagnosed hebephrenic or paranoid schizophrenics, and my 3 affective cases 2 manic and 1 depressive. (I combine hebephrenic and paranoid schizophrenia because of the difficulty in laying down mutually exclusive diagnostic criteria.)

Thus the patients with epilepsy developed 8 paranoid or hebephrenic-like conditions, 1 depressive and 2 manic conditions as compared with 103 paranoid and hebephrenic schizophrenics and 17 manic or circular and 95 depressive affective conditions in the patients with illness of comparable duration without epilepsy.

These figures show no statistically significant difference in their relationships but when taken in conjunction with Alstrom's figures (6), which include no affective breakdown they are suggestive that the relationship between the number of affective illnesses and schizophrenic illnesses in epileptics is less than in the epileptic free population. It also appears that chronic depressive psychoses severe enough to produce delusions are extremely rare in epileptics. There is a suggestion that the classical belief that religious delusions are common in epileptics may be based on a particular clinical pattern as in cases 10 and 11, which automatically grouped themselves in my category of hypomanic affective psychosis, comprising the entire group.

Of the schizophrenic group, 7 out of 8 have clinical and/or EEG evidence suggesting temporal lobe epilepsy and of the affective group 1 out of 3. This when compared with figure of 1 in 5 of the general epileptic population as given by Jasper, *et al.* (14), supports the theory that there is a relationship between psychosis following epilepsy and temporal lobe dysfunction.

The absence of evidence of an altered incidence of schizophrenia or schizophrenic-like condition in epileptic subjects from the general population and the evidence suggesting an increased incidence of temporal lobe epilepsy in the psychotic patients considered, suggests that epilepsy in patients who are liable to schizophrenia tends to manifest itself in the temporal lobe.

SUMMARY AND CONCLUSIONS

From a study of the literature and of the cases suffering from epilepsy which later developed chronic psychoses with delusions, no evidence was found to support either of the hypotheses implicit in earlier writings that schizophrenia occurs more, or less, frequently in epileptics than in the general population, but there was a suggestion that affective psychoses occur less frequently, that depressive psychoses are very rare and that hypomanic psychoses may take a typical form of a divine revelation followed by elation and Messianic delusions. This last category is the only evidence to suggest a typical chronic epileptic psychosis.

No case suffering from a paranoid reaction of sufficient severity to satisfy my original criteria, that could not be classified as affective or schizophrenic, was found.

The high incidence of clinical and/or EEG evidence implicating the temporal lobe, supports the view that psychosis following epilepsy is related to temporal lobe dysfunction.

It is suggested that epilepsy in subjects liable to schizophrenia tends to manifest itself in the temporal lobe.

APPENDIX

THE CASES

I. Schizophrenia

CASE 1.—Mrs. G.L.K. Aged 35 years. Temporal lobe epilepsy, possibly relative to birth trauma, developing a psychosis in the late 20's indistinguishable from schizophrenia with hebephrenic and paranoid features. Coincidental with the development of the psychosis there was disappearance of the epilepsy.

CASE 2.—Miss D.E.L.L. Aged 32 years. Epilepsy, possibly idiopathic, with myoclonic features developing slowly a schizophrenic-like psychosis with a fairly well marked affective element. (Sphenoidal electroencephalography was not carried out).

CASE 3.—Mr. A.G.T.S. Aged 41 years. Sustained 2 severe head injuries, with a paranoid schizophrenic-like illness showing clinical and EEG evidence of temporal lobe epilepsy. The epilepsy commenced when patient was 11 years old, and the psychosis 27 years later. The head injuries post-dated the onset of epilepsy by 10 and 12 years.

CASE 4.—Miss E.T. Aged 21 years. Temporal lobe epilepsy as a result of a complication of whooping cough, probably vascular, aged 1½ years, with a markedly abnormal personality developing into a paranoid schizophrenic-like illness. The

dated from childhood while the psychosis lasted a little over one year's duration.

CASE 5.—Miss O.M. Aged 22 years. Epilepsy with EEG evidence suggesting the origin in the temporal lobe, developing a paranoid schizophrenic type of illness. The epilepsy may have been post-traumatic, or a doubtful head injury may have resulted from an epileptic attack. The epilepsy dated from childhood and the psychosis had a duration of 5 years.

CASE 6.—Miss F.M.S. Aged 24 years. A typically schizophrenic type of psychosis developing in a patient with long standing epilepsy clinically very suggestive of temporal lobe origin without definite EEG proof, but with EEG and AEG suggesting the left hemisphere as the source. The epilepsy commenced when the patient was 2 years old. The psychosis was of 3 years duration.

CASE 7.—Mrs. D.C. Aged 32 years. Clinically temporal lobe epilepsy with later EEG evidence of temporal lobe foci, developing a paranoid schizophrenic-like illness with depressive features, within a few years of the onset of the epilepsy.

CASE 8.—Mr. L.W.H. Aged 43 years. Long standing (at least 30 years duration at onset of psychosis) epilepsy, temporal lobe in origin on clinical and EEG evidence. He developed a paranoid schizophrenic-like illness. This case is the nearest to a pure paranoid state in the series as the delusions tended to be systematised around one idea, but he showed definite loss of conceptual thought and incongruity of affect, and therefore is legitimately classified with the paranoid schizophrenic group.

II. Paranoid Reactions—Nil

III. Affective Psychosis

CASE 9.—Miss F.K.T. Aged 47 years. A chronic depressive psychosis in a patient of low intelligence with long standing (10 years at the onset of psychosis) epilepsy of obscure origin—possibly idiopathic.

CASE 10.—Mr. J.M.C. Aged 45 years. Chronic hypomanic state with religious and messianic delusions commencing soon after the onset of epilepsy when he was 36 years old. EEG evidence points to the epilepsy originating in the temporal lobe.

CASE 11.—Miss B.L. Aged 36 years. Symptomatic epilepsy following an undiagnosed (? venous thrombosis) organic lesion of the right side of the brain, aged 18 months, developing an affective psychosis mainly hypomanic, the delusions and hallucinations being mainly concerned with a religious theme and including the idea that she had a divine message which it was her duty to impart to the world.

IV. Dementia

CASE 12.—Miss J.S.C. Aged 41 years. An acute dementing condition with delusions and hallucinations developing a few years after the onset of epilepsy, aged 17 years. In spite of a normal EEG and cerebral biopsy the picture remains doubtful.

A STUDY OF THE TRANSFER OF LONG-HOSPITALIZED PATIENTS TO A CONVALESCENT SERVICE

FREDERICK PHILLIPS, M. D., AND SOPHIA BELLE MAY, M. A.¹

Chronic patients in state mental hospitals (however "chronic" may be defined) are usually patients who live in wards less adequately staffed, and consequently less active therapeutically and socially, than other wards in the hospital. They are, therefore, a group about whom less is known during the course of hospitalization, than is known of other patients.

In order to learn more about this group, 72 male patients at Spring Grove State Hospital, almost three-quarters of whom had been in the hospital from 5 to 45 years and all of whom were considered to require prolonged hospitalization, were studied. In obtaining information about the patients, the staff also learned something about the functioning of the hospital. Out of this study was born a new conception of the role of the mental hospital.

ORIGIN OF PROJECT IDEA

Early in the winter of 1952, members of the professional staff expressed concern about the many inadequacies of the poorly defined and organized hospital work program and proposed a study of a small group of patients employed in the hospital to obtain factual information.

The area selected for study was a Convalescent Cottage, the first unit to be occupied of 4 newly erected modern cottages, each planned to house about 50 patients. They were intended to serve as a convalescent service, a new concept in the hospital's existing architectural and administrative scheme.

Cottage I was opened in November 1952 with the transfer of male patients from the Continued Care Service, where many had for years lived in one of two old and overcrowded buildings. They were chosen for their ability to live on an open ward with a minimum of supervision and personal care.

Those who first came to Cottage I then, while not truly convalescent, unless one might say "chronically convalescent," had been able to maintain at least a minimally independent existence within the hospital.

This cottage was chosen for 2 reasons: 1. more men than women might be expected to be engaged in hospital work assignments off the ward; and, 2, it was a group sufficiently small numerically and segregated geographically to separate for study.

CHANGE IN FOCUS

Before the study actually began the original idea was expanded to include ways of stimulating these patients to become more socially active and if possible as a result of this experience, to leave the hospital.

At the end of 2 years, by July 1, 1955, 26 of the 55 patients considered eligible to leave the hospital (as described later in this report) had done so: 18 in foster care, 9 by parole to their families or outright discharge, and one by elopement. Of the 26, only 3 were again in the hospital July 1, 1955. Not only had 52% of those considered able to leave actually moved into the community but 25 of the 26 were economically self-sufficient during their convalescent leave. Only one patient required tax-supported assistance, obtaining an old age assistance grant.

The immediate, practicable results, encouraging though they were, turned out to be less important than the long range effect of the ideas precipitated by the project—ideas that touched off basic changes in hospital thinking. The final report, therefore, is written to highlight the impact on the project group of this intimate, concentrated experience with chronic patients. Analysis of factors influencing patients' ability to leave and to remain out are left to a subsequent report.

STRUCTURE OF THE PROJECT

Spring Grove State Hospital is the third oldest state mental hospital in the United

¹ From the Spring Grove State Hospital, Baltimore 28, Md.

States, with an average in-patient population of 2800, distributed at the time the project was undertaken in an Admission Building, a small proportion in the infirmary and other services, but the majority housed in 2 continued care services. The new, modern convalescent cottages and a treatment building for women patients had just been completed.

Staff was inadequate but no more so than usual in state hospitals. Because Spring Grove is close to psychiatric centers in Baltimore and Washington and because its superintendent and clinical director provided progressive, patient-oriented leadership, the hospital had become a training center for all related professions: nursing, psychology, social work and psychiatry. The staff consequently was more than usually treatment conscious. A foster care program, therapeutic rather than custodial, had been in operation since 1941. The social service department had already considerable experience with long hospitalized patients, but largely those who had some motivation to leave and had been individually referred.

STAFF

The staff engaged in the study consisted of a psychiatrist, chief of the men's continued care service, who initially administered the convalescent cottages, the nursing supervisor of the convalescent service, a vocational counsellor from the division of vocational rehabilitation, and a case work supervisor. The latter devoted half time to this project and served as co-ordinator and recorder of its activities. The project began February 1, 1953 and continued to July 1, 1953, where all the staff participants, except the nurse, assumed responsibilities elsewhere; no service was, therefore, available to the patients after July 1 which was not already provided for in the convalescent service.

Cottage I designed for 50 patients, is a modern, spacious brick building with some double rooms and some small dormitories, with its own dining area, seating 4 at a table, and several rooms for recreational purposes. In size and comfort, it is in dramatic contrast to the buildings from which the patients came. Before the project officially began, the

psychiatrist transferred to other buildings those patients who were too deteriorated to participate actively in cottage activities. In their place came 4 patients from the admission building, 2 long hospitalized patients who were transferred as reward for faithful service, and 2 who had been admitted 7 and 11 months respectively before this transfer.

The project involved 72 patients, 49 of whom were continuously resident in Cottage I from February 1 to July 1, 1953. Thirteen were transferred to Cottage I between February and July, 6 from the continued care service and 7 from the admission service. Five of these 7 were admitted after January 1, 1953 and had, therefore, a different relation to hospital residence than the rest of the group. They were, however, expected to require prolonged hospitalization. Eleven left the Cottage during these 5 months, 7 to live in the community and 4 transferred to other buildings.

METHOD

The methods developed from actual experience and not without fumbling. To provide for interchange of ideas and a truly collaborative effort, the staff members met weekly during the first month, and thereafter irregularly. However, there were frequent conferences between the social worker and other members of the team.

Weekly group meetings were held with the patients to give them an opportunity to discuss their own ideas about living in the new building and to raise whatever problems they wished. The meetings, held from February 3 through May 26, were voluntary with an average attendance of 20 to 25. They were conducted by the psychiatrist, with the social worker serving as participant observer.

Beginning in March, weekly staff meetings were held to interview individual patients, usually 3 at each meeting. All members of the team participated in these conferences at which time the history was reviewed, the patient interviewed and the thinking of the various disciplines pooled to plan for further diagnostic or treatment measures. In addition, patients had planned individual contacts with the staff: 6 with the vocational counsellor, 5 with the doctor, 23 with social

workers and 8 with psychologists for testing.

The social worker recorded the staff planning meetings, the patient group meetings and, from all sources, filled out a card on each patient containing face sheet data, activities in the hospital, staff recommendations, etc. to be used for statistical reference. The psychiatrist dictated a summary of the staff conference for the patient's chart.

FACE SHEET INFORMATION

Ages ranged from 18 to 81 but this was predominantly an older group (47% over 50); hospital residence ranged from a few months to 45 years (71% more than 5 years, 53% more than 10 years and 20% more than 20 years.)

DIAGNOSIS

Fifty-eight per cent (42 patients) were schizophrenic, 17% (12) mentally defective (not psychotic), 15% (11) chronic brain syndromes (lues, Parkinsonism, arteriosclerosis, etc.) and about 10% (7) manic-depressive, involutional and reactive depressions.

PATIENTS' EXPERIENCE AND ADJUSTMENT IN THE HOSPITAL

When the staff inquired about the patients' experience in the hospital, little reliable or consistently recorded information was available. Nursing notes were meager; and the charts often contained only fragmentary data. Certain facts like hospital employment, other information, and paroles rarely appeared. From a cursory check, so few charts had recent progress notes that a survey was made of all the charts to note the date of the last progress note prior to February 1, 1953 (see Table 2).

The interval between progress notes, prior to the last, was also likely to have been long (5 to 11 years). The material recorded in one chart states in full: 1/15/35—"Works as one of the night men in the boiler house. Takes little interest in surroundings. Patient does not disturb his environment." 2/14/42 "Hands well." In another chart appeared: 3/12/42—"Foot better." 1/23/48 "Blood Wassermann positive." In still an-

other: 3/2/49 "Infection around nail." 1/12/53 "Abscess of molar with general anesthetic."

As an additional check on the use of the patient's chart, a survey was made of the last occasion prior to February 1, 1953 that the chart had been signed out of the record room. (Records are filed centrally. Three years previous to the project a system of signing them out had been initiated).

The charts of 26 patients (36%) had not been taken out of the record room in 3 years.

TREATMENT

Treatment was defined as specific "psychiatric" therapy: shock treatment of various kinds, anti-luetic therapy, occupational therapy, and individual or group psychotherapy. Medical and surgical treatment for physical ailments not directly related to the psychiatric condition was not included. The data were secured from the charts. Hopefully, other treatment was given but not recorded.

From the time of their admission to February 1, 1953, 23 patients had had one or more of the specific psychiatric therapies, as defined above. Fourteen had had a course of electroshock therapy, 4 anti-luetic, 13 indi-

individual or group psychotherapy and 10 occupational therapy. Only 2 patients hospitalized over 5 years had received either occupational or group psychotherapy.

If the time during which treatment was given is limited to the 5 years immediately preceding February 1, 1953, only 15 patients (21%) had had psychiatric treatment. The length of residence in the hospital of these patients is interesting: (See Table 3).

Contact with Families.—Patients hospitalized longer than the staff expected had retained contact with their families. Regular contact with some family member, even if infrequent, was considered as retaining contact. Eight patients had no known relatives. Of the remaining 64, 22 no longer had contact (see Table 4).

However, the quality of that contact—retention of the family as a resource when hospitalization ends—seemed to undergo a change with the passage of time, the family gradually excluding the patient as a family member even while continuing interest in him. (This is expressed in the way the patients did leave. Of the 19 patients retaining contact with their families who left by July 1955, 6 of 7 hospitalized less than 5 years returned to their families while only 3 of 12 hospitalized more than 5 years did so.)

Hospital Employment and Privileges.—Only little more than one-half of these "open ward" patients prior to February 1953 worked off the ward. (Eleven of these 37 received pay from the hospital ranging from \$2 to \$25 a month.) Twenty patients worked exclusively on the ward. Fifteen did no work.

TABLE 4

Length of residence	Total	Retaining contact	Percentage
	64	42	63
Less than 5 yrs. ..	19	17	89
More than 5 yrs. ..	45	25	56

Some of the patients on the hospital payroll had responsible jobs: one as supervisor of the hospital print shop, another as relief switchboard operator, etc. Three patients were working 12 hours, 7 nights a week at the power house. Others had been operating for years in jobs well below their present potential.

All 72 patients transferred to Cottage I were presumed well enough to handle ground privileges and the doors were left unlocked. However, 8 never left the ward, 27 remained on the hospital grounds (24 of these had never asked for greater freedom) and 37 occasionally or frequently made trips into nearby towns.

Previous Residence in the Community.—Five patients had been placed in foster care and 4 paroled to their families at some time prior to 1953. They had remained out from 10 to 228 days. Nine others had previously been referred to social service for help in making plans to leave but all declined the opportunity to return to the community.

Ward Adjustment.—The patients had been selected for the cottage because they were considered able to live with others with only minimal supervision. Although their behavior varied from seclusiveness, with considerable psychotic preoccupation, to a fair degree of social integration, the general attitude was of human beings living quite separately from one another. Watching TV was the major leisure-time activity. About 12 went to the hospital movies and dances. About the same number regularly read newspapers and magazines but few books. Gardening occupied 4 and a few played ping-pong or worked on jig-saw puzzles.

Ability to Live Outside the Hospital.—Although many patients functioned in routine fashion, often below their actual capacity and with little stimulus for change provided, many were making a marginal or better adjustment to the social demands within the hospital, social demands at least resembling the expectation of the outside world. But for few did this ability seem to create any wish to leave. Up to this point, the staff had used the usual criteria for parole planning: the patient's capacity to function adequately within the hospital in terms of the

resources outside in family or community for his care, and the degree of the patient's motivation to leave.

These criteria resulted in all too familiar half-answers as reasons against parole for many of the 72 patients. For instance, the staff found themselves saying, "These men are too afraid to leave," or "No one would give him a job," or "That patient's sister does not want him to leave." The "essential" seemed to the group to lie in the "definition" of the hospital itself as a treatment and/or protective service for the mentally ill.

The facts so far indicated that treatment, in any active sense at least, had seemed to diminish drastically with the years in the hospital. As a matter of fact, the longer the patient was in the hospital, the less likely was the staff to know much about him. The pattern bears a suggestive correlation to the parole probability figures of the National Institute of Mental Health.²

The staff, then, shifted the criteria of parole readiness from the *patient's* resources to the *appropriateness* of hospitalization as a service and reformulated the questions. Is the patient dangerous to himself or others? Is he likely to benefit either from the treatment available in the hospital or from the protection it affords? If not, then he should not be in the hospital.

With these new criteria, the psychiatrist, nurse and social worker without consultation with each other each compiled a list of patients able to live outside. The social worker listed 50 patients who could leave, the doctor 55 and the nurse 60. When the lists were compared, there was agreement regarding about 47 patients. Each had a few patients also on another's list; each had a few on no other list. (Interestingly, no patient had left the hospital 2 years later who was not originally on all 3 lists.)

The staff group agreed, after discussion, on 55 patients able, on the basis of this new formula, to leave the hospital. It was not assumed, of course, that these patients could return to the community without consider-

able help from their families or through foster care program. Nor was it assumed that any appreciable number, at this late date in their lives, would choose to make the attempt, even with help. The implications of this review were, however, startling. Fifty-five of 72 patients, or 76%, no longer required hospitalization. How much more could existing hospital facilities achieve for the 24% still requiring hospitalization if time and energy were not expended on the other 76%.

OUTCOME OF PROJECT

Of the 55 patients considered able to leave, only 7 were immediately interested and left the hospital by July 1, 1953. Eleven demurred but thought they might be willing to leave later. (By July 1955, 10 had left and the last was well on the way.) But 37 out of 55 (66%) rejected the idea. They were too frightened to talk about it or they said, "I have too much to lose. I can't expect to have it so good outside." Or "Why didn't you ask me 10 years ago?" (By July 1955, 9 did, after all, leave—5 died. None of the 5 admitted after 1/1/53 left.)

As the project progressed there was noticeable improvement in about 70% of the patients with greater sociability and more relaxed and pleasant contacts with personnel. Those patients working 7 nights weekly were given 2 days off each week and improvement in their ward adjustment was noted.

Much was left undone. The fact that the project was time-limited rather than a continuing service has itself certain serious implications. If, as it seemed to the staff, the major gain was the fact that 72 patients became individualized, many for the first time in years (with the possibilities this created for thoughtful planning, stimulation—and hope—for patients and staff), the gain itself is a sad commentary on how much is lost on countless chronic wards where such attention is not available.

Within the limitations imposed on the majority of state hospitals, what might be done to prevent this waste in human life and productivity?

² Facts and figures about mental illness and other personality disturbances. Bethesda, Md.: Natl. Inst. of Mental Health, April 1952.

WHAT MAKES PATIENTS "CHRONIC?"

In spite of the fact that the number of patients in this study is small, the information obtained cursory and the methods of intervention used pathetically meager, nevertheless, the thoughts provoked by the experience may have some validity for others concerned with long hospitalized patients and may at least been suggestive to the hospital in which the study occurred.

Tentatively, chronicity might be described as an impaired but relatively stable level of adjustment existing over an extended period and involving, finally, an unwillingness or inertia about effecting any change. Mental illness may be chronic without necessitating hospitalization at all or remain chronic following hospitalization, impairing as it so often does the individual's ability to get along with others.

Mental illness may be chronic at a much lower level of adjustment than was true of the patients in Cottage I. But even with residual symptoms, prior experience in the foster care program at Spring Grove indicates many such patients can maintain a satisfying life outside the hospital walls.

Precisely because many of the patients in Cottage I were able to function in relation to job, social activity and living with others, although sometimes in a minimal fashion, the question arises as to whether this is chronicity in a medical or, primarily, in a social sense, having less to do with the course of the illness and more to do with the way these men lived together, for a considerable time, in a particular kind of community—the mental hospital.

Facts about progress notes, psychiatric treatment and contact with family for these 72 patients do suggest that after 2 years, hospital activity in connection with the patient's recovery begins to ebb and a substantial difference is apparent after 5 years.

Timing is undoubtedly an important factor in the delicate balance between the patient's and family's satisfaction and dissatisfaction with living in Spring Grove as an accepted and, finally, an essential way of life.

Satisfaction with life in the hospital, especially when it compares favorably to what

may be available outside, is a necessary ingredient. New buildings, active recreation programs, etc., may even deepen this pattern for many without sufficient staff or a community-pointed convalescent program.

The loss of identity as an individual plays a large part in furthering chronicity. Limited staff, over-crowded buildings, the inaccessibility of records, as well as the patients' own desire to remain unnoticed promote a protective kind of anonymity. Even for those patients who call themselves to the staff's attention as "nuisances," "amusing characters" or "helpful souls," personal identity is lost in the stock roles they play.

The staff's own expectation is probably one of the most telling factors in this whole problem, an expectation absorbed into patient mores and circulated back to the staff. Spring Grove, as well as other state hospitals, seems to be in a transition between 2 hospital "cultures:" the old concept of asylum with its function of protective custody, and the new concept of temporary care during a specific treatment program. One culture is emerging from but has not yet displaced the other.

The patients described in this project span these 2 philosophies. Many began their hospitalization during the "asylum" period. They were cared for, even if the quality of care was sometimes deplorable. Conformity to hospital mores resulted, after a period of years, in stagnation—witness the progress note, "Patient does not disturb his environment," which was not followed by a referral to social service for help in leaving. Today, more than likely, such referral would result. Patients, faced by this inexplicable change in hospital attitude, express themselves resentfully, "I've worked for the hospital for 20 years; now they want to get rid of me." Or, as one patient, disturbed by the suggestion he leave, rushed to the superintendent to complain, "I was born and raised in Main Building [an old chronic service] don't let them take me away!"

For many years the hospital will have residents from this generation of "chronics." Slowly, ways may be found to help some of these "frozen" ones to leave but, more im-

portant, ways may be found, need to be found, to avoid creating future generations of such patients.

SUMMARY

For five months a staff group of psychiatrist, social worker, nurse and vocational counsellor worked closely with a group of 72 male patients, about 75% of whom had been hospitalized more than 5 years but who were currently able to maintain, with little supervision, a minimal social level of adjustment at least. The patients had recently been transferred from old buildings to a modern convalescent cottage. Twenty-six patients, who might otherwise have stayed indefinitely, did leave but 29 others—or a total of 55 patients of the 72—actually were no longer receiving any active benefit from hospitalization. A differentiation seemed pertinent

between chronicity of the illness itself and social chronicity in which the individual becomes adapted to a routine level of social functioning below his actual capacity. The culture of the state hospital seems to invite chronicity in the latter sense.

The study indicates some of the threads in this pattern—often implicit rather than explicit. Chief among them is perhaps the old conception of the state hospital's function to give shelter indefinitely to those for whom no obviously better plan is available in the community and who are not motivated to try.

The study suggests a concept of hospitalization limited to the continuing appropriateness of that service in terms of treatment and/or protection and some of the administrative means by which the social adjustment of the patient might then be stimulated to keep pace with the expectation of future plans to live outside.

EFFECTIVE UTILIZATION OF ELECTRIC CONVULSIVE TREATMENT

PETER F. REGAN, M.D.¹

Some of the problems involved in the correct timing of the use of insulin and electric convulsive treatments have recently been clarified by Hill(3). Greaves, *et al*(2) have demonstrated the specific psychopathologic situations in schizophrenic reactions in which insulin treatment works most effectively. It is the purpose of this report to delimit the psychopathologic situations in which electrically induced convulsions may be expected to produce satisfactory or unsatisfactory results. When these results are joined with those of current investigations of the effectiveness of chlorpromazine and other pharmacologic treatments, it is hoped that the varied physical treatment tools available to the psychiatrist may be used in efficient, complementary fashion.

CASE MATERIAL AND METHODS

This report is an analysis of 200 unselected cases that received electric convulsive treatment (ECT) at the Payne Whitney Psychiatric Clinic. For the past 10 years, ECT has been used as a symptomatic adjunct to psychotherapeutic treatment. For the most part, it has been administered to relieve depressions or to control excitements. In such instances, ECT was introduced after a psychotherapeutic relationship had been established, when the symptoms interfered with further psychotherapeutic progress; the timing of ECT administration was, therefore, usually similar to that described by Hill(3). In some instances, severe excitements forced the use of ECT at an early stage in treatment, or ECT was used as a last resort in chronic illnesses.

When used in depressions, ECT was administered twice a week, and when used in excitements, it was administered daily for a series of 2 to 5 treatments. Atropine sul-

phate 0.6 milligrams was administered one hour before treatment. On a few occasions, curare or tubocurarine was used with ECT; this study does not include patients treated with succinylcholine. The convulsion was produced with the use of 60-cycle alternating current delivered through bitemporal electrodes by standard Medcraft ECT machines (Models B2 and B24). The voltage ranged from 100 to 160 volts, and the current was applied for 0.1 second to 0.6 second. The figures in this report refer to treatments administered; occasional missed convulsions are counted as treatments.

In the analysis of case material which follows, most terms are self-explanatory. The term "psychopathologic condition" refers to the characteristics of the patient's emotional, intellectual, and behavioral state at the time ECT was administered. The psychopathologic condition is determined in accordance with the principles outlined by Diethelm(1) which involve a synthesis of the observable personal and social functioning with a thorough knowledge of the conscious and unconscious dynamic significance of the functioning for the individual.

Degree of improvement has been determined by the application of the following criteria: a patient was considered unchanged if illness was not improved in any observable fashion; mild improvement indicates that symptoms decreased to the extent that he could live with slightly increased comfort in a hospital setting; moderate improvement indicates that a patient was still partially incapacitated by symptoms; marked improvement indicates that the patient achieved freedom from symptoms. Improvement rates have been determined for the patient's condition at termination of the first or the only course of ECT, and at discharge. For all determinations, the author has relied on personal contact, examination of clinical records, and the personal evaluation of the clinic's psychiatrist-in-chief.

¹From the Department of Psychiatry, Cornell University Medical College and the New York Hospital (Payne Whitney Psychiatric Clinic), New York City

RESULTS

Identifying Characteristics.—The sex distribution of the 200 patients (131 female, 69 male) was in accordance with over-all hospital distribution. As is commonly the case in voluntary hospitals, protective environments had delayed hospitalization of many women, and more of them had chronic illnesses; this factor must be considered in evaluating the finding that the men had a better improvement rate than the women (Table 1) at the time of termination of ECT (92.8% vs. 82.5%) and at discharge (85.5% vs. 62.5%). An acute onset is associated with better outcome than is gradual onset at termination of ECT (94.8% vs. 80.7%) and at discharge (82.9% vs. 67.3%). Similarly, illnesses of less than one year's duration have a better improvement rate at termination of ECT (92.5% vs. 76.1%) and at discharge (79.5% vs. 61.1%).

With 100 patients under 40 and 100 patients between 41 and 79 years of age, it is clear that the older group improves more than the younger at termination of ECT (92% vs. 80%) and at discharge (82% vs. 65%). The great majority of the younger patients, however, were those with schizophrenic reactions, many gradual in onset and chronic in nature; it seems doubtful, there-

fore, that age in itself has such a significant effect.

Treatment Characteristics.—Most patients remained in treatment in the hospital from 3 to 9 months (Table 2). The duration of hospitalization was not reflected in the effectiveness of ECT, all lengths of stay being associated with similar improvement rates at the termination of ECT; those patients who needed to remain longer than 6 months, however, had a poorer outcome at time of discharge.

ECT^{*} was administered to 102 patients with 3 months, to 68 with 3 to 6 months, and to 30 with more than 6 months of hospitalization. One hundred sixty-eight patients received one course of ECT, 28 received 2 courses, 2 received 3 courses, and 2 received 4 courses. The total number of treatments administered to a single patient ranged from 1 to 37 (Table 2), most patients receiving 5 to 12 ECT. No significant differences may be observed in improvement at termination of ECT except for those patients who received less than 5 treatments. On the other hand, those who required only 5 to 8 ECT had a better improvement rate at discharge

TABLE 1

FACTORS IN IMPROVEMENT

1. Identifying characteristics

Character- istics	Number of patients	Patients improved at termination of ECT	Patients improved at discharge

Weight loss ...	26	22 (84.6%)	19 (73.0%)
No change	9	5 (55.6%)	5 (55.6%)
Not known	46	—	—

83.7%) than did those who required more ECT; those who required more than 16 ECT had a lower improvement rate at discharge (50.3%) than any other group with more than 4 treatments.

Subcoma insulin treatment was given in conjunction with ECT in 25 instances, 17 in patients with paranoid schizophrenic reactions; the improvement rates are not significantly different when results are compared. Weight change was studied in 154 patients (Table 2); an increase in weight during treatment was associated with greatest rate of improvement (92.4% at termination of ECT and 81.5% at discharge); decrease in weight was associated with poorer results (84.6% at termination of ECT and 73.0% at discharge); no change of weight was associated with the poorest percentage of improvement (55.6% at termination of ECT and at discharge) in the 9 patients in whom it was observed.

Diagnostic Categories.—ECT was administered to 62 patients with depressive reactions (7 of these occurred below age 40, and 5 were part of a manic-depressive reaction), 7 patients with manic excitements, 85 with schizophrenic reactions, 17 with paranoid reactions, 20 with psychoneurotic reactions with depression, and 9 patients with other conditions (such as confusional state, and epilepsy).

Marked deviations from the over-all effectiveness of ECT become apparent when the effect of treatment in these diagnostic categories is considered (Table 3). The improvement rates for the entire group are 86% at termination of treatment and 73.5% at discharge. Patients with affective disorders, paranoid reactions, and psychoneurotic reactions with depression, however, have improvement rates of 95.1%, 94.1%, and 90%, respectively, at termination of treatment; similarly they have improvement rates of 86.9%, 76.4%, and 85%, at discharge. In contrast, the patients with schizophrenic reactions show improvement rates of 80% at termination of treatment and 61.1% at discharge. Even with the group of schizophrenic patients, there is wide variation in accordance with diagnostic sub-categories,

Total	200	172 (86%)	147 (73.5%)

and a lack of consistency between results at termination of treatment and at discharge.

Emotional Status.—When the emotional status of the patient is considered, a similar deviation from over-all improvement rates is apparent. A total of 111 patients in all diagnostic categories received ECT when the predominant emotional state was depression; these patients had improvement rates of 91.8% at termination of treatment, and 81.9% at discharge (Table 4). Further investigation revealed deviations from this pattern, depending on what other psychopathologic condition or emotion was most prominently associated with depression. For the 81 depressed patients whose most prominent secondary characteristic was paranoid features, anxiety, agitation, fear, or marked sexual disturbance, the improvement rates were 97.5% at termination of treatment and 91.3% at discharge. For the 30 patients whose most prominent secondary characteristic was hostility (including aversion and negativism), guilt, or body overconcern, the improvement rates were 76.6% at termination of treatment and 56.6% at discharge.

Totals III		102 (91.8%)	91 (81.9%)

* A—Affective reactions; NPS—Non-Paranoid schizo-
phrenic; O—Other; PN—Psychoneurotic reaction; PR—
Paranoid reaction; PS—Paranoid schizophrenic reaction.

In the remaining 89 patients, whose pre-
dominant emotional state was not depression,
the improvement rates were 78.6% at termi-
nation of treatment, and 62.9% at discharge.
In 61 of these patients, certain psychopatho-
logic conditions were predominant (Table
5), of which, only fear and marked sexual
disturbance appear to afford better improve-
ment, with respective rates of 92.3% and
80% at termination of treatment, and 69.2%
and 73.3% at discharge. Hostility would
seem to indicate a good initial response to
ECT, with a rate of 84.6% at termination of
treatment, but a poor eventual result, with a
rate of 53.8% at discharge. With anxiety
and fixed conditions with little affect, results
seem poor.

FACTORS IN IMPROVEMENT

5. Interaction of diagnostic category and psycho-
pathologic condition

Diagnosis and condition	Number of patients	Patients improved at termination of ECT	Patients improved at discharge
Affective reaction			
a. Depression with paranoid features, anx- iety, agitation, fear or sexual content 51	51	51 (100%)	48 (94.1%)
b. Depression with hostility, guilt, or body concern 11	11	8 (72.7%)	6 (54.5%)
Totals 62	62	59 (95.1%)	54 (87.0%)

whose depression was associated with paranoid features, anxiety, agitation, fear, or sexual content, the improvement rate at termination of ECT was 100%, and at discharge was 94.1%. In contrast, the 11 patients whose depression was associated with hostility, guilt, or body concern had improvement rates of only 72.7% at termination of treatment, and 54.5% at discharge. The latter 11 patients accounted for 5 and the former 51 patients accounted for 3, of the total of 8 patients who did not improve.

This significance may be further examined by studying the degree of improvement among the 51 patients whose depression was associated with paranoid features, anxiety, agitation, fear, or sexual content; 33 (64.7%) had achieved marked improvement at termination of treatment, and 35 (68.6%) at discharge. In contrast, among the 11 patients whose depression was associated with hostility, guilt, or body concerns, only 2 (18.1%) had achieved marked improvement at termination of treatment, and 3 (27.2%) had at discharge.

DISCUSSION

Increasing experience with the newer pharmacologic methods of treatment indicates that no one of these drugs is universally applicable. Like electric convulsive treatment and other physical methods, they operate most effectively within certain spheres of psychopathology. Moreover, they share with other physical treatments the quality of acting symptomatically. When they are viewed in the broad field of physical treatment in psychiatry, therefore, it would seem inadvisable to attempt to supplant one physical treatment with another, or to regard any treatment yet developed as being fundamentally curative. Instead, each physical method, old and new, should be studied most intensively, in order to determine the specific situations in which each will work most effectively, and the time at which it can most effectively be integrated into a psychotherapeutic regimen.

If specific situations in which the different physical treatments offer maximal help are to be delineated, it seems apparent that the use of diagnostic categories to describe illness is not enough; the fact is that all

schizophrenic reactions, or all depressions, are not identical. Instead, increasing attention must be paid to the dynamic psychopathologic state of the patient. It is well recognized that the same emotions, attitudes, and symptoms occur in different diagnostic categories. Thus, hysterical features may be found in psychoneuroses, schizophrenic, and affective reactions, as may anxiety, or depression. Extensive psychoanalytic investigations have revealed that such psychopathologic conditions have specific dynamic and therapeutic characteristics. Investigations have also revealed, however, that the major diagnoses have equally specific dynamic and therapeutic characteristics. The qualities of the psychopathologic condition, therefore, will be merged with those of the diagnostic category. The result of this mixture will determine the therapeutic availability, the prognosis, and the optimal treatment of the individual patient.

It was the purpose of this study to determine whether or not an investigation of this interaction would contribute to a more efficient utilization of ECT, and would indicate its place in the armamentarium of psychiatric treatment. The findings require substantiation and extension with larger groups of patients. At this point, they confirm the impression that ECT will be most effective in those illnesses whose predominant feature is depression, but indicate clearly that this effectiveness is modified by the diagnostic category and the associated psychopathologic findings. Thus, greater effectiveness is achieved in affective reactions, less in paranoid and psychoneurotic reactions, and least in schizophrenic reactions. A similar differential effectiveness obtains for psychopathologic conditions: depression associated with paranoid features, anxiety, fear, agitation, or sexual content will respond to ECT with far better results than will depression associated with hostility, guilt, or body concern. Maximal effectiveness is achieved when depression with the first group of associated conditions is found in a patient with an affective reaction.

If depression is not present, diagnostic category and psychopathologic condition still modify the results of ECT. Fear and sexual content augur good results, while anxiety or

fixed conditions make a poor result likely. Even within schizophrenic reactions, catatonic stupors and excitements associated with fear or sexual content will respond well. In each of these conditions, however, the difference between improvement rates at termination of ECT and at discharge is a striking indicator of the fact that ECT remains a symptomatic treatment, and that ultimate results depend on the total therapeutic situation.

When the differential effectiveness of ECT is compared with that of chlorpromazine, some therapeutic possibilities begin to appear. Chlorpromazine has proven most effective in relieving hostility, whether with or without depression; initial studies at this clinic indicate that it may be possible to use chlorpromazine to control hostility until psychotherapy has relieved its pressure, and that ECT may then be useful if indicated for treatment of depression. Similarly, the apparent effectiveness of meprobamate in relieving anxiety may prevent the need for using ECT in its presence. If we are to utilize some of these leads, however, it would seem imperative that there be further intensive studies of the differential effectiveness of each physical treatment.

SUMMARY

This study is concerned with the effectiveness of ECT as an adjunct to the psycho-

therapeutic treatment of 200 patients. It is found that effectiveness depends both on diagnostic entity and psychopathologic state. Thus, affective disorders responded best to ECT; paranoid reactions and psychoneurotic reactions with depression responded well; and schizophrenic reactions poorly. Influencing these results, however, was the fact that depression associated with agitation, anxiety, fear, or sexual content yielded better results, and depression associated with hostility, guilt, or body concern yielded poor results, in each diagnostic category. In the absence of depression, fear and sexual content yielded good results, and hostility, anxiety, and fixation yielded poor results. Optimal efficiency was obtained only when ECT was indicated by both diagnosis and psychopathologic state.

It seems essential that information about differential effectiveness be determined for each of the physical treatments available in psychiatry. Only thus will it be possible to achieve maximum effectiveness and complementary utilization of these treatments.

SENSORY DEPRIVATION

A REVIEW

PHILIP SOLOMON, M. D.,¹ P. HERBERT LEIDERMAN, M. D.,² JACK MENDELSON, M. D.,³ AND DONALD WEXLER, M. D.⁴

It has long been known through autobiographical writings that explorers and shipwrecked individuals who undergo isolation for many days may suffer curious mental abnormalities. In recent years it has been found that prisoners-of-war exposed to "brainwashing" may experience similar fates. Since perceptual and sensory deprivation seem to be basically involved in each instance, a number of investigators have begun to approach the subject experimentally. This article is a critical review of some of the most pertinent autobiographical, "brainwashing," and experimental data.

AUTOBIOGRAPHICAL REPORTS OF ENVIRONMENTAL STRESS

Admiral Byrd(1) wanted "to taste peace . . . quiet and solitude long enough to find out how good they really are." He spent 6 months alone in the Antarctic. Dr. Alain Bombard(2), who wished to prove that shipwrecked people could survive at sea for an indefinite length of time, sailed alone across the Atlantic Ocean for 65 days on a life raft, subsisting solely on what food he could get from the sea. Both men, dedicated scientists, reacted to their isolation and loneliness in almost identical fashion. The lack of change in their environment caused a monotony which was oppressive, and they felt themselves drawing deeply into themselves for emotional sustenance.

Both explorers found that while their lives were threatened daily by the hazards of

their milieu, it was the constancy of their surroundings which seemed like a force which would destroy them. Both men felt that they could control themselves and their environment only by thoroughly organizing their days, assigning themselves to a strict routine of work, and spending no more than one hour at a time doing a task. In this way, each felt he proved to himself that he could control both himself and his environment.

After 3 months alone, Admiral Byrd found himself getting severely depressed. He felt a tremendous need for "stimuli from the outside world," and yearned for "sounds, smells, voices and touch." Bombard, too, "wanted terribly to have someone . . . who would confirm any impressions, or better still, argue about them . . . I began to feel that . . . I would be incapable of discerning between the false and the true." Both men used the same mechanisms to fight off depression: controlling their thoughts, dwelling only on pleasant past associations and experiences and refusing to allow themselves to think about the anxiety-producing aspects of their situations.

Hallucinations and delusions as well as depression and anxiety play a prominent part in the accounts of other individuals under severe stress and isolation. Christine Ritter in her very sensitive document, "A Woman in the Polar Night,"(3) reported that at various times she saw a monster, and heard ski strokes on the snow where no one was evident. Pseudo-hallucinatory experiences occurred in which the "imprisoned senses circled in the past, in scenes without spatial dimensions," and at one point during the long arctic night she experienced depersonalization to the extent that she thought she and her companions were "dissolving in moonlight as though it were eating us up. The light seemed to follow us everywhere," and "neither the walls of the hut nor the roof of snow can dispel my fancy that I am moonlight myself." The Spitzbergen hunters

⁴ Assistant in psychiatry, Harvard Medical School, assisting physician in psychiatry, Boston City Hospital.

used the terms *rar* (strangeness) to describe these experiences. They are reported by many who spent the winter in polar regions.

In discussing the effects of being alone in the Arctic (she would be alone for periods up to 16 days) Mrs. Ritter makes the interesting observation that

the extraverts among those who spend the winter here will always intrinsically create for themselves a sphere of activity and hence a sphere of reality, which will save them when no impulse comes from without. Those who find their pleasures in meditation, will withdraw into themselves, into regions of astonishing brightness; but those who are accustomed to yield to their inclination to idleness run the great danger of losing themselves in nothingness, of surrendering their senses to all the insane fantasies of overstretched nerves.

In 1943 Jan Baalsrud(4), a Norwegian soldier saboteur, while fleeing from the Nazis, spent 27 days alone on a mountainous plateau where he had to be left by friends who had rescued him. Because of frostbitten feet, he was unable to move from his sleeping bag. For at least 20 of these days, he was buried by a blizzard, his only sustenance for most of the time being a teaspoonful of brandy daily. He saved the last spoonful as a symbol of his continuing hope for survival. Within the first 36 hours he thought he heard the sound of skis and he shouted to people he thought were present. He felt that his brain was clear. . . .

his mind was occupied with the minute details of physical existence; to keep moving, to be on the watch for frostbite, to stop the snowroof from falling down. . . . Each of these tasks became an absorbing activity . . . and each an important part of his conscious effort not to die. When any of the tasks were accomplished, he felt he had warded off death for a few minutes. He sometimes visualized death as a physical being who prowled about him. He parried the lunges (of) this creature . . . and he was proud . . . when he thrust off . . . its attacks.

Tales of the sea have provided many accounts of hallucinatory phenomena. Capt. John Slocum(5) sailed alone around the world. During a gale in the South Atlantic he reefed his sails rather than take them down. Restricted to his cabin because of sickness he suddenly saw a man, who at first he thought to be a pirate, take over the tiller. This man refused to take down the sails on request from Slocum, but instead reassured

him that he was a pilot and would safely take his boat through the storm. The next day Slocum found his boat on true course 93 miles along. Later that night the pilot returned in a dream and reassured him that he would come whenever needed. For the remainder of the voyage during gales this apparition appeared to him several times.

Walter Gibson(6), a soldier in the British Indian Army, was on a ship torpedoed in the Indian Ocean by the Japanese in World War II. Of 135 survivors, there were only 4 alive one month later and he was the only Caucasian among them. Under the most extreme conditions of physical deprivation and partial social isolation Gibson reported that "all of us at various stages in that first week became a prey to hallucinations." Dreams which became prevalent at about the same time were "fierce and vivid dreams of food and drink and family gatherings." As the conditions became more extreme the feeling of comradeship disappeared and the men began to find themselves "watching our fellows covertly and suspiciously." Murder, suicide and cannibalism followed as social controls dissolved. Finally, some 4 weeks later after landing on an island, "the faces of person after person who had been on the boat appeared around me on the rocks and stones on the beach."

Gibson makes the important point that survival experiments on rafts and lifeboats, when the men know that they are never in real danger, are not comparable to the situation when men are facing the unknown alone and without knowledge of the end. He thus emphasizes the inherent difficulties in comparing natural situations with experimental studies.

BRAINWASHING

Major-General William Dean(7) was as unwilling a subject for perceptual isolation as Byrd and Bombard and Ritter were enthusiastic volunteers; yet his experiences were in many ways similar to theirs. He was kept apart from all other United Nations' prisoners and although he was under constant observation by North Korean guards he felt completely alone. He had great difficulty in preserving his judgement. "You have no

one on whom to test your ideas . . . a thought which you would normally discard . . . balloons in your mind until you are sure it must be exceptionally clever."

A physical fitness enthusiast, General Dean did calisthenics—even when reduced to crossing and uncrossing his fingers because of orders forbidding him to exercise, and he did algebraic problems in his head (as did Bombard). These activities made the General feel that he was maintaining his intellectual and physical integrity. Nonetheless, at one point during his imprisonment, he became so depressed that he attempted suicide.

Thought control, or "brainwashing"(8), a phenomenon which has existed in civilization for centuries, has taken on a new and sinister meaning, as seen from the experiences of both political prisoners and prisoners of war who have been held in prisons operated by the Russian and Chinese Communist governments. Lifton(9), describing the Chinese method, believes that "milieu control" is the element added to thought reform techniques which makes the latter so effective. He says "The Chinese Communist prison is probably the most thoroughly controlled and manipulated group environment that has ever existed . . . milieu control eliminates any possibility of reality testing or consensual validation."

Schein(10) and Lifton(11) describe how environmental manipulation was begun as the POWs were transferred to camps run by the Chinese Communists. Officers and non-commissioned officers were sent to separate camps, depriving the enlisted men of leadership and discipline. The enlisted men were further segregated according to race and nationality. They were told that they were war criminals and that therefore their rank and the unit to which they belonged no longer had meaning. Any organizations established by the POWs to maintain discipline and to ferret out intelligence were broken up by informers. The men who showed qualities of leadership were sent to separate camps.

The receipt of mail from home was regulated so that the POW was allowed to receive only those letters which were pessimistic about the outcome of the Korean Conflict

or indicated a lack of interest in the POW or the conflict. Such letters depressed the men. They lost interest in mail from home and tended to lose identification with their families. The men were made so suspicious of one another that the buddy system which had enabled soldiers in Japanese and German POW camps in World War II to maintain morale, became ineffectual. Informers and Chinese spies were so numerous the men felt that the only way to protect themselves was to withdraw from all intimacy with other prisoners.

As a result of such efforts, the goal of the Chinese Communist indoctrination, to make the men into a "group of isolates," was partially achieved. "The most important effect of the social isolation . . . was the consequent emotional isolation which prevented a man from validating any of his beliefs, attitudes and values through meaningful interaction with other men." Each man was on his own life-raft.

Once social and emotional isolation was achieved, indoctrination was begun. The only sources of information available to the POWs in Korea and to civilian prisoners in Red China, were Communist publications, motion pictures and radio broadcasts. These had to be discussed and studied until the prisoner could prove that he understood and accepted them. Communist ideas were repeated again and again until the prisoner, fatigued and half-hypnotized, accepted them as the truth.

Even after being returned to the United States, civilians who had been prisoners in Chinese Communist prisons for 2 to 4 years sometimes repeated their false confessions. They insisted that they were guilty of "crimes against the people" and praised the "truth and righteousness" of Communist doctrine.

According to Lifton, the basic tenet of thought reform was that each prisoner was a "reactionary spy" who must die and be reborn "in the Communist image." For the first 1 to 3 months the prisoner was interrogated almost constantly, either by "judges" or by his 7 or 8 Chinese cell mates organized into a team of inquisitors, whose purpose was to "help" the prisoner make his confession. The environment was completely or-

ganized so that every act of the prisoner was made known to the authorities. Routine was so thoroughly prescribed that even the time for toilet needs was set.

After 2 or 3 months of such treatment, in addition to suffering from physical fatigue and illness, the prisoner was usually very confused, "unable to clearly demarcate the boundaries of truth and fiction." He was depressed "frequently to the point of being suicidal," and sometimes experienced psychotic symptoms, "such as auditory hallucinations."

Once the prisoner had "confessed," to being an enemy of the people, his reeducation began. He was forced to participate in study groups which lasted 10 to 16 hours a day, taking up almost all of his waking hours. Every question or problem "must be solved by the group by means of discussion," in which the prisoner must examine his shortcomings or errors in belief and judgement. For years, until his education had progressed to the desired point, the prisoner spent his life in a cell so small that when the inmates (the prisoner and the 7 or 8 Chinese who formed the confession team) wished to turn over while sleeping at night, they could do so only together at a given signal from the team leader. Little wonder that gradually the "external milieu replaced the internal milieu." The prisoner under such a system is in a situation very similar to that described by George Orwell in "Nineteen Eighty-Four(12)."

Somewhat in contrast to Lifton and Schein, Hinkle and Wolff(13), in their survey of Communist interrogation and indoctrination methods, emphasize the importance of isolation as the major technique. They point out that

when the initial period of imprisonment is one of total isolation . . . the complete separation of the prisoner from the companionship and support of others, his utter loneliness, and his prolonged uncertainty have a further disorganizing effect upon him. Fatigue, sleep loss, pain, cold, hunger, and the like, augment the injury induced by isolation. . . . With the passage of time, the prisoner usually develops the intense need to be relieved of the pressures put upon him and to have some human companionship. He may have a very strong urge to talk to any human and be utterly dependent on anyone who will help him or befriend him. At about this time he also becomes mentally dull and loses his

capacity for discrimination. He becomes malleable and suggestible and in some instances he may confabulate.

Stypulkowski(14), in his autobiographical account of interrogation for several months by the Russians in Lubianka Prison, Moscow, graphically reiterates Hinkle and Wolff's findings.

In addition to milieu control in "brainwashing," the role of Pavlovian reflex psychology has been discussed by Meerloo(15) and the relationship to drive reduction mechanisms has been emphasized by Winokur(16) and by Santucci and Winokur(17).

The presence of a common denominator of *imposed control of external stimuli*, whether it be the reduction of news from the outside world or enforced solitary confinement, appears to be a factor of primary significance. Christopher Burney(18) expressed succinctly the effects of such control. He was an English army officer engaged in espionage in Occupied France during World War II and he was kept in solitary confinement by his German captors for 18 months. He said, "I feel a sense of impotence, an inexorable subjection to a machine of nameless horror." He added "Variety—is the very stuff of life. We need the constant ebb and flow of wavelets of sensations, thought, perception, action and emotion—keeping even our isolation in the ocean of reality, so that we neither encroach nor are encroached upon."

EXPERIMENTAL STUDIES

Walter(19) feels that the nervous system requires constant extrinsic sensory input to function normally and efficiently. While studying neural mechanisms and behavior in situations involving alterations of perceptual stimuli, Lilly(20) proposed the question: "Freed of normal efferent and afferent activities, does the brain soon become that of coma or sleep, or is there some inherent mechanism which keeps it going, a pacer-maker of the awake type of activity?" Lilly approached the problem by experimentally reducing the *absolute intensity* of physical stimuli received by a human subject. This was accomplished by suspending a subject, wearing only a blacked-out head mask for

breathing, in a tank of water maintained at 34.5 degrees centigrade. With this technique, visual, auditory and tactile stimuli were reduced to a minimum. A variety of results occurred, some involving highly personalized fantasy material and projection of visual imagery.

Experiments carried out in Hebb's laboratory by Bexton, Heron and Scott(21) attempted the *reduction of patterning* of stimuli to low absolute levels. Healthy college students were placed on a comfortable bed in an airconditioned soundproof cubicle. The subjects' arms and hands were enclosed in cardboard cuffs to minimize tactile stimuli and their eyes were covered with translucent glasses which permitted entry of light but abolished all pattern and form vision. Observation of these subjects revealed the following: after several hours, directed and organized thinking became progressively more difficult; suggestibility was greatly increased; the need for extrinsic sensory stimuli and bodily motion became intense; most subjects found they could not tolerate the experiment for more than 72 hours; subjects who remained longer than 72 hours usually developed overt hallucinations and delusions. In description these were similar to those reported with mescaline and LSD.

Thus by reduction of patterning of stimuli it was noted that a series of mental abnormalities could be produced experimentally and that in many instances the severity and progression of symptoms could be related to the length of time of the sensory deprivation.

Heron, Doane, and Scott(22) subjected themselves and 5 other subjects to similar experimental conditions for a period of 6 days. All subjects had visual disturbances for 12 to 24 hours after being removed from the experimental situation, as follows: there were fluctuations, drifting, and swirling of objects and surfaces in the visual field; change of position of object occurred with change in eye or head movement; shapes, lines and edges appeared to be distorted; visual after-images were accentuated; colors were very bright and there was exaggeration of contrast phenomena.

Electroencephalograms taken during the period of sensory deprivation revealed slower

frequencies in the alpha range and marked delta wave activity. The records were still abnormal 3½ hours after the subjects were removed from isolation.

Experimental deafness has been reported by Ramsdell (in Hebb)(23) and by Hebb, Heath, and Stuart(24). In these cases cotton wool with petrolatum was placed in the ears of subjects for 3 days. Their chief findings, with marked individual differences, were: inability to speak with normal volume; increased and decreased motivation for studying; marked irritability; exaggerated response to stimuli; desire either to withdraw from situations or to charge into them; feelings of personal inadequacy. There was no evidence of fantasy behavior, though one subject reported that she spoke to a group and no one seemed to hear her.

The reduction of patterning of stimuli has been employed by investigators studying the effects of isolation in the therapy of mental illness(25). These studies, however, are of limited value because of the many variables associated with selection, diagnosis and evaluation of mentally ill patients in an experimental procedure.

The most recent reports of the effects of sensory deprivation involve clinical observations made on a group of 9 patients with poliomyelitis who required treatment in a tank-type respirator(26). In these cases, the mental abnormality began after the patient had been in the tank for 24-48 hours or longer, and was characterized by well-organized visual and auditory hallucinations and delusions to which the patient reacted in different ways and to different degrees. Most of the patients referred to these experiences as dreams. They could recall them in detail even many weeks later. Although many illnesses which affect the nervous system, and indeed many without direct nervous system involvement, are capable of producing abnormality of mental function, they are usually associated with some evidence of a febrile, anoxic, toxic or metabolic derangement. As far as could be determined, there were no such factors in these patients.

The hypothesis formulated was that the abnormality of mental function was related to perceptual isolation or restriction imposed by the unique conditions of life in a tank-

type respirator. The significant findings were:

1. Well-organized delusions and hallucinations occurred only in poliomyelitis patients treated in the tank-type respirator.

2. They required 2-7 days to develop in overt form.

3. The condition lasted 10-15 days and recovery was independent of recovery of motor function or of continued existence in the respirator.

4. In all instances fever was absent, no drugs were being given, and no metabolic aberrations could be demonstrated.

5. Disorientation was the common substrate. The content of the experiences could be pleasant or horrendous, but only rarely was there psychomotor agitation as seen in toxic-infective delirium. In all patients the symptoms were worse at night, and better during the periods for feeding, physiotherapy, and visiting.

6. The patients were able to recall their experiences with great vividness and detail even many weeks after the symptoms ceased. Most of the patients were unable to recall the events of their more lucid intervals in the respirator.

To understand this disorder, it is necessary to consider the unique situation presented by life in a tank-type respirator: vision is restricted to a limited area; the patient never sees any part of his own body; the dominant auditory stimulus in a respirator ward is the rhythmic machine-like sound of the tank motor and the bellows; the patient lies constantly in the same position, and even if not paralyzed, moves his limbs very little.

Thus the patient is restricted in terms of visual, auditory and kinesthetic sensation, and suffers a corresponding degree of perceptual deprivation. This deprivation was different from Lilly's *reduction of the absolute level of stimuli* and Hebb's *reduction of the patterning of stimuli*, though essential elements of both were present. It could be termed an *imposed structuring of stimuli*, for the stimuli the patients received were both unvarying and repetitive, yet were not reduced in absolute level of intensity. Also, form and pattern discriminations were not abolished. This imposed structuring of

stimuli has characteristics analogous to the structuring of the external milieu noted in "brainwashing" techniques, described above.

Recent experiments using human volunteers in a tank-type respirator in our laboratory(27) have added further evidence in confirmation of the effects of perceptual deprivation under these conditions.

At the present time both experimental studies and clinical observations on sensory deprivation need further and more careful investigation. Many factors require additional evaluation and many variables in experimental design and technique must be controlled. Attempts to repeat certain phases of experimental procedure have shown that perhaps even small variations can yield diametrically opposite results. The changes in experimental design utilized by Vernon and Hoffman(28) in attempting to repeat the McGill group's observations illustrate this. These investigators were not able to elicit the findings reported from Hebb's laboratory, as described above, but they admitted they had not employed exactly similar methods. It remains to be determined what items in the experimental situations are the key elements.

In the area of experimental investigation of sensory deprivation, more carefully refined data are necessary before any basic hypothesis can be supported or rejected. Future investigations should attempt to contribute data of both quantitative and qualitative adequacy.

SUMMARY

Sensory deprivation has been produced experimentally by reducing the absolute intensity of stimuli, by reducing the patterning of stimuli, and by imposing a structuring of stimuli. Explorers have experienced it voluntarily and prisoners have had it thrust upon them.

While there are many separate factors operating in these various situations, it is clear that the stability of man's mental state is dependent on adequate perceptual contact with the outside world. Observations have shown the following common features in cases of sensory deprivation: intense desire for extrinsic sensory stimuli and bodily

motion, increased suggestibility, impairment of organized thinking, oppression and depression, and, in extreme cases, hallucinations, delusions, and confusion.

Though the basic concepts regarding perceptual and sensory deprivation are not new, their recent importance in experimental and real life situations has made them increasingly interesting. Future studies in this area may well contribute to our knowledge of the psychological and behavioral patterns of man under conditions of normality and stress.

CLINICAL NOTES

A COMPARISON OF PHENAGLYCODOL (ULTRAN), MEPROBAMATE AND A PLACEBO IN ABSTINENT ALCOHOLICS¹

JACKSON A. SMITH, M.D.,² AVONELL RUTHERFORD, R.N.,³ AND RITA FANNING, R.N.⁴

The major problem in the treatment of the alcoholic is not the immediate relief of the discomfort following an alcoholic bout, but finding a preparation which will prevent the patient's taking the drink which initiates the next episode. A preparation which would decrease emotional lability or afford subjective relief from tension, and which would create no undue hazards of habituation would be very desirable in the treatment of these patients.

For this purpose the effects of two ataraxics and an identical placebo have been compared in the treatment of 45 chronic male alcoholics, 32 of whom were committed to a state mental hospital, and the remaining 13 were seen in an outpatient alcoholic clinic.

Using a "double blind" procedure, the medications and placebo were prepared in identical capsules and were given orally t.i.d. in the following order to each patient for a 2-week period: phenaglycodol 300 mgm., placebo, and meprobamate 400 mgm. Placing the interval during which the patients received the placebo between the two active medications afforded an opportunity to compare both with the inactive substance.

The 32 inpatients were seen following admission to the hospital by a research nurse. Initially, the patient's statements as to his reasons for drinking and evidence of tension or anxiety were recorded as were his sleeping habits, dreams, appetite and ability to retain food. His pulse and blood pressure

were taken and the presence of a tremor, perspiration or restlessness were noted. The medication was then started and 6 weekly interviews were done in the same manner during the study.

Results.—It was planned to compare an equal number of clinic and hospitalized patients, but it soon became apparent that the medication and the brief interview were not sufficient to motivate the clinic patients to return and only 3 of the 13 outpatients completed the course.

Twenty-six of the inpatient alcoholics were believed to have completed the study, 2 escaped from the hospital, one discontinued treatment, and 2 were apprehended discarding the medication. Seven of the 26 who completed the study slept better and were less tense while taking the active preparations than when receiving the placebo. Nine stated they slept better at night, but complained of drowsiness during the day when they were on placebo. Eighteen patients who either slept better, were less tense or had a better appetite, showed the same improved state on phenaglycodol, meprobamate and placebo.

This study reflects the difficulties in evaluating a treatment for chronic alcoholism. The inpatients improved after admission and attributed their improvement to the medication, but they showed no significant change when an identical placebo was substituted nor when a second active compound was added. Several others became drowsy or improved on an inactive placebo.

The outpatient group emphasizes the importance of motivation; it is likely that a larger number would have completed the study if a better relationship had been established with the patients. It is equally likely that the resulting prolongation of their

¹ This study was generously aided by a grant from Eli Lilly & Co. All the medications used in this study were furnished by Eli Lilly & Co.

⁴ Nurse, Research Ward, Nebraska Psychiatric Institute, Omaha, Neb.

abstinence would have been the result of the relationship rather than the tranquilizer being given.

In this "double-blind" study of a group of 45 chronic alcoholics treated during their

abstinent period, there was no significant clinical change observed in their behavior nor in their subjective state, whether they were receiving phenaglycodol, meproamate or placebo.

THE MECHOLYL TEST AS A PREDICTOR OF IMPROVEMENT IN INSULIN COMA THERAPY

HARRY VANDERKAMP, M.D.,¹ ANNE NORGAN, M.D., GLADYS W. WILKINSON, R.N.,
AND DAVID PEARL, Ph.D.

The present study aimed to assess the prognostic value of various mecholyl chloride reaction indices for insulin coma therapy with emphasis on immediate improvement rather than on the long range effectiveness of treatment. Previous investigators of this test have relied primarily on systolic blood pressure changes as a criterion. Since these are influenced by many extraneous factors, other potentially useful variables such as pulse rate and diastolic blood pressure changes, sweating, salivating, flushing, pupillary changes and global reactivity were also employed. Serum cholinesterase levels were also evaluated.

Subjects were 125 male schizophrenic patients referred for insulin coma therapy. Prior to insulin treatment, basal blood pressure and pulse rate measurements were taken following which subjects were given a 10 mg. injection of mecholyl in the deltoid muscle. Systolic, diastolic blood pressures and pulse rates were gauged at 2, 5, 7, 10, 12, 15 and 20 minutes following the injection. Sweating, salivating, flushing, pupillary change and global reactivity were separately rated on five point scales with gradations ranging from no change to marked responsiveness. From this larger group, only those patients were utilized who subsequently completed 30 or more insulin comas. Seventy-five subjects meeting this criterion were then rated on a five point scale of improvement by the insulin ward physician who had no knowledge of these patients' responsiveness to mecholyl chloride.

Correlational and Chi square analyses of the relationship of mecholyl reactivity varia-

bles and insulin improvement were carried out. Both pulse rate and systolic blood pressure deviations from basal measurements were significantly related to the extent of therapeutic change, whereas diastolic blood pressure alterations were unrelated. Pulse rate deviations generally show higher correlations than systolic blood pressure measurements. The magnitude of correlation for both variables rises and then diminishes as the time interval following drug injection increases. Maximum correlations occur after 7 minutes, pulse rate deviations correlating .63 and systolic blood pressure deviations -.34 with insulin improvement. The maximum pulse rate deviation shows a significant correlation of .37 with improvement, a relationship not found for maximum systolic blood pressure changes.

Such variables as sweating, salivating, flushing and global reactivity were found to be significantly related at the P.05 level to insulin improvement categories. Global reactivity correlated +.70 with improvement while each of the other three variables correlated .42. Multiple correlations of improvement, pulse rate deviation and various of the other variables were not significantly greater than the simple correlation between pulse rate and improvement.

When subjects were grouped into systolic blood pressure categories according to criteria enunciated by other users of the test, patients fell into two major groups, one of category II and III subjects and the other of category V and VI subjects. A tetrachoric correlation of .40 was found between these categories and insulin improvement, category V and VI subjects showing significantly greater improvement than the others.

¹ Veterans Administration Hospital, Battle Creek, Mich.

No significant differences were found between improved and non-improved subjects for cholinesterase delta ph units and a biserial correlation of .02 was determined between improvement and this variable.

Results suggest strongly that the mechoyl test has prognostic value for improvement in insulin coma therapy and that the commonly utilized variable of systolic blood

pressure changes have a lesser relationship to improvement than several other measures. The pulse rate deviation variable being relatively objective and reliable, is probably the best index. In this study its predictive power was significantly greater than the Funkenstein test index of systolic blood pressure groupings, suggesting its possible value for prediction of improvement with other therapies.

UNEXPECTED ASPHYXIAL DEATH AND TRANQUILIZING DRUGS

LEO E. HOLLISTER, M.D.¹

Two recent contributions to this journal have suggested that tranquilizing drugs were responsible for asphyxial death in some patients (1, 2). A plea was made for further information about this possible complication of tranquilizing therapy.

In Table I, I have compiled all the unexpected asphyxial deaths at a 1325-bed neu-

ropsychiatric hospital in the past 6½ years. This sample is complete since any unexpected death comes to autopsy. Deaths from aspiration pneumonia terminating a long downhill course were excluded. Only those cases were included in which either the mode of death or its time was not expected. The midpoint of the series, 1954, was the year in which tranquilizing drugs were started on a large number of our patients.

This type of death has been no more com-

mon during the period of tranquilizing drug therapy than before. What is particularly noteworthy is the high incidence of asphyxial death in patients with brain damage, particularly those with convulsive disorders. Such an association of brain damage and unexpected asphyxial death was clearly present even before tranquilizing drugs were used.

Of the 3 patients who died while on tranquilizing drugs, only 2 deaths raised the possibility of tranquilizing drugs being a contributory factor. The 66-year-old syphilitic who died in 1957 had had numerous near-fatal aspirations prior to being placed on prochlorperazine. The 43-year-old man who died in 1955 appeared to have drowned during a convulsion while swimming. He had been receiving chlorpromazine without any previously noted increase in seizure frequency. The 34-year old woman who died in 1957 had been on intensive chlorpromazine therapy. The day before her death she had a seizure (though she had others recorded before receiving chlorpromazine) and was placed on anticonvulsants. The following day she was found dead less than an hour after the evening meal. Although food particles were present in her trachea, the amount was insufficient to have caused major obstruction. Death was attributed to glottal

spasm from a seizure and irritation from aspirated food.

In some of the previously reported deaths of this type, the possibility of a concomitant seizure was entertained. Since it is perfectly possible for patients to die from asphyxia in seizures, without any tranquilizing drugs, the problem is to decide in what way tranquilizing drugs might influence the frequency of this complication. The most logical possibility is that these drugs (reserpine or rauwolfia alkaloids, chlorpromazine or other phenothiazine derivatives) may induce seizures. Many reports already in the literature attest to seizures being either aggravated or produced *de novo* by these agents. The only study of the effect of long-term drug therapy with reserpine on the swallowing mechanism showed no impairment when an objective test was used (3).

The moral seems to be: the risk of using tranquilizing drugs may be increased in brain-damaged patients or those with known seizures. This increased risk should be measured against the potential benefit from the drug.

HISTORICAL NOTES

I REMEMBER C. K. CLARKE

1857—1957

It may be that only a few veterans in psychiatry will remember that Canada owes her most eminent figure in this field to a murder.

As 1957 marks the hundredth anniversary of the birth of Charles Kirk Clarke it is a proper time to refresh our memories of this remarkable man.

It was during the asylum epoch, when psychiatry was exclusively state medicine, when politicians exploited the institutions for the insane, and when the superintendents of these institutions were political appointees. This is not to say that there were no good men as heads of the asylums. Dr. Clarke—"C. K." as we respectfully clipped his name—was especially fortunate in his first appointment in the provincial service to come under the influence of a man (Dr. Joseph Workman, superintendent of the first asylum in Ontario, located at Toronto), to whom he always paid homage as a great leader who had helped more than anyone else to shape his own professional career.

The chain of events leading to Clarke's adoption of psychiatry for a career was like this: 1. Senior assistant Metcalf at the Toronto Asylum took a warm interest in young Clarke and the two became close friends; Metcalf later married Clarke's sister. 2. In due course Metcalf was sent as superintendent to the Asylum at Kingston, Ontario where a heavy task of reorganization awaited him. 3. Clarke, who in the meantime had become assistant superintendent at the Hamilton Asylum, was detailed to Kingston in a similar capacity, where he and Metcalf combined their efforts to bring some kind of order into asylum practice. 4. After 3 years in Kingston Clarke had had 11 years experience of the deplorable state of asylum affairs under political control and he decided to quit. "I love psychiatry but hate politics," he said. His resignation was in the hands of the government. 5. It was now 1885. Clarke and his

chief are making ward rounds. A patient rushes at them and stabs Metcalf fatally. Metcalf was 38 years old, Clarke 28. 6. At the request of the government Clarke withdraws his resignation and takes over his dead chief's job. Having put his hand to the plough he now resolves to see it through to the end of the furrow.

My first acquaintance with Dr. Clarke was during the meeting of the British Medical Association in Toronto in 1906. At this time C. K. was the head of the institution where he had served his apprenticeship under Workman. One of the notable features of that meeting was a visit to the Toronto Asylum where it was possible to observe the improvements and new features that had been inaugurated under the wise administration of Dr. Clarke. That evening he entertained at dinner guests from Britain and the United States.

The great versatility of Dr. Clarke is reflected in the variety of positions he was called upon to fill. Thirty-seven years he had given to the provincial hospital service, 26 of these years as superintendent, during which he set the pattern for modern mental hospital organization and administration. About the turn of the century, there was developing in his mind the concept of a psychiatric hospital affiliated with the University of Toronto, where not only clinical study and treatment but also training and research might be carried on. Here would have been the first such clinic in the country. Dr. Clarke's forward looking plans and forthright criticism of reactionary and *laissez-faire* policies aroused jealousies and obstructionist activities in the service and among the politicians. Before action could be taken came the explosion of World War I and the dream, which if realized would have been a conspicuous monument to C. K.'s superior leadership, failed of fulfillment.

Meanwhile the University had made him

the first professor of psychiatry (1906), and dean of the medical faculty (1908-1920). Next came the request that he accept the superintendency of the newly created Toronto General Hospital and in 1911 he left the provincial service to assume that position, which he held through World War I. In the absence of the head of the department of psychology on military service, Dr. Clarke had charge of that department as well as of the department of psychiatry.

When the Canadian National Committee for Mental Hygiene—now the Canadian Mental Health Association—earliest offspring of the parent organization in New York City, was founded in 1918, C. K. became the first medical director and continued in that office while he lived. He also created the pioneer outpatient psychiatric clinic at the Toronto General Hospital. During the last 20 years of his life he was a member of the editorial board of this JOURNAL, the first Canadian to be elected to the board.

To go back a little, one of Dr. Clarke's earliest measures to improve the condition of hospital patients, dating from his first superintendency in 1885, was the establishment of a very practical form of occupational therapy. He set up at Kingston shops for various industries, chiefly broom and brush making. Here many patients were employed and soon Kingston was supplying these utensils not only to the other asylums in the province but to the open market as well. Of course the inevitable happened. Organized labour raised a howl that this was unfair competition. The howl reached the ears of parliamentarians in Toronto and instructions were sent to Dr. Clarke to curtail his mischievous activity in providing healthful occupation for his patients. Politics again!

Clarke was not only a medical statesman and a great humanitarian; it is fair to call him the father of Canadian psychiatry. He was a man of many interests; he was a proficient musician and organized his own string quartette. He even designed and built a pipe organ which was long in use. Near to his heart was the welfare of students and as dean of the medical faculty of the University of Toronto he was the beloved friend of

the students of that faculty. The lighter side of their life was represented by an annual performance staged by them in the university theatre. It was—and is—called Daffydill and, like *Twelfth Night*, was "What You Will." For once in the year the students could with immunity poke fun at their professors in public. Those professors, more than likely, were there to enjoy the jokes at their expense. Certainly C. K. was there. Indeed he was a promotor of Daffydill and contributed to the program.

Dr. Clarke was vitally interested in problems of immigration and was disturbed by the inefficient control or lack of control of the influx of undesirables from Europe. At his request Professor W. A. Smith of the department of psychology at the University of Toronto undertook a detailed study of Canadian immigration. This work was published in book form in 1920. In his introduction to this book Dr. Clarke characterized the record as "a chapter of tragedy and mismanagement." He condemned in strong, if not always diplomatic language, the inadequacy of immigration regulations. "It has ever been true that the failures of the old world have sought and have been encouraged to seek pastures green in the new world, without the slightest consideration of the reasons why they have not succeeded at home. . . . Those of us who are making surveys of thousands of school children, have long ago learned, however, that the descendents of these poor types fall far below the average and are simply adding to our anxieties rather than helping to build up a healthy people." One wonders what Dr. Clarke would say if he were available for comment on present conditions of immigration.

My most intimate association with C. K. was during a tour of inspection of the mental hospitals of the Dominion during World War I. Returned soldiers with psychiatric disabilities and needing further hospital treatment had at first been sent to their home provinces to be cared for in the provincial institutions. The federal department responsible for the disposal of invalided soldiers, then known by the mouth-filling title, Department of Soldiers' Civil Re-establishment, required a report on all matters relating to these vet-

erans scattered across Canada. It was desirable that one inspector outside the government should be engaged; Dr. Clarke was the obvious choice, and it was my privilege, as chief psychiatrist for the Department, to be associated with him on this tour. Beginning with British Columbia, institutions in the 4 western provinces were comfortably surveyed, provincial and hospital authorities offering every possible assistance. In Winnipeg word reached us that Dr. Clarke would not be permitted to visit any of the Ontario hospitals. In his home province which he had served so faithfully and so long and with such splendid results he was *persona non grata* as far as the government of the day was concerned.

One of Dr. Clarke's last public functions was the delivery of the Maudsley Lecture on psychiatry before the British Medico-Psychological Association in London. He was the only Canadian to whom this honour had fallen.

Born in 1857 C. K. died much too soon in 1924. Visiting him in his final illness I found him sitting up in bed busily engaged in constructing a hammock destined for a special use. He was one who could do things with his hands as well as with his head. He talked of the work of his department, and future plans just as if he might be carrying out these plans himself. He spoke of the psychiatric clinic he had hoped to see built before World War I, and of his plans for its organization. It was a touching moment when he said that he had nominated me as his successor.

At the memorial service in the University's great convocation hall it was the president, Sir Robert Falconer, who paid the tribute. His first sentence he spoke slowly and let it stand alone for a few seconds: "Charles Kirk Clarke was a good man."

His friends who listened knew the profound meaning of those words.

C. B. F.

DISCIPLINE OF THE EMOTIONS

"Refuse to express a passion, and it dies . . . on the other hand, sit all day in a moping posture, sigh, and reply to everything with a dismal voice, and your melancholy lingers. There is no more valuable precept in moral education than this . . . if we wish to conquer undesirable emotional tendencies in ourselves, we must assiduously . . . go through the *outward movements* of those contrary dispositions which we prefer to cultivate. The reward of persistency will infallibly come. . . . Smooth the brow, brighten the eyes, contract the dorsal rather than the ventral aspect of the frame, and speak in a major key, pass the genial compliment and your heart must be frigid indeed if it do not gradually thaw!

—WILLIAM JAMES

CORRESPONDENCE

ELECTROSHOCK AND HYPOTHALAMIC SYNDROME

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: In the June 1957 issue Dr. John C. Pollard reported a case showing an unusual hypothalamic syndrome with complete vasomotor collapse following electroshock therapy. The effect of EST on the autonomic nervous system has been of interest to me for some time. In a paper appearing in the *Psychiatric Quarterly* (Observations on Electric Shock Treatment, *Psych. Quart.* 17, 327-336, April 1943) I reported two patients with symptoms attributed to irritation of the autonomic nervous system, one of whom showed severe emaciation, multiple skin abscesses not responding to surgical treatment,

and trophic changes of nearly all fingers and toes, and died within two months after termination of EST. My conclusion was that EST produces severe stimulation of the autonomic nervous system.

A search of the literature, as Dr. Pollard has stated, fails to reveal additional cases, although it seems likely that other investigators might have had similar experiences. Much of the improvement brought about by electroshock and its more recent modifications can be explained by its effect upon the vegetative nervous system; similarly, it can be readily understood that adverse reactions are also possible.

KURT NUSSBAUM, M. D.,

BENACTYZINE (SUAVETIL)

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: I have read with interest Doctors Vernon Kinross-Wright's and John H. Moyer's article in *The American Journal of Psychiatry*, 114: 73, July, 1957, describing their experience with the tranquilizer benactyzine (Suavetil).

About two years ago Lloyd, Dabney & Westerfield Laboratories were kind enough to let me try benactyzine in my general psychiatric practice. I tried it for over a year in over 80 patients, including all types of psychiatric cases, and came to the same con-

clusions that Doctors Kinross-Wright and Moyer did.

It was occasionally effective in reducing anxiety and tension in emotionally disturbed patients. So many of the patients reported atropine type side-effects, however, that it was difficult to get them to continue medication in sufficient dosage to give them much symptomatic relief. After a year's trial with benactyzine, it was discontinued as being less effective than other tranquilizers and objectionable to the patients because of its side-effects.

FREDERICK LEMERE, M. D.,
Seattle, Wash.

DRUG FATALITIES

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: This letter refers to Paul E. Feldman's case report, "An Unusual Death Associated With Tranquilizer Therapy," in the

May 1957 issue of *The American Journal of Psychiatry*.

The following case report is from the psychiatric division of the Kings County Hospital Center, Brooklyn 3, New York. It suggests, as did Dr. Feldman's report, the

failure of the cough reflex to respond adequately to foreign material in the trachea.

Case History.—A 30-year-old schizophrenic female was hospitalized on April 8, 1957. The onset of her mental illness was relatively acute. Clinically, hyperactivity, agitation, hypochondriacal delusions and hallucinations were observed. At the time of admission and for most of her hospitalization she remained agitated, had a low-grade fever (100-100.6 rectally) and sinus tachycardia. The remainder of her physical examination and laboratory tests including blood urea nitrogen determination, complete blood counts and urinalysis were within normal limits. Chest and thoraco-lumbar vertebrae X-ray studies were normal.

Thorazine, 200 mgm. q.i.d. by mouth was begun on April 10, 1957. There was no untoward initial response to the drug. On the day of the patient's

death she had her last dose of Thorazine at 2 p.m. At 6 p.m., shortly after the patient had dinner she was observed in the day hall markedly dyspneic and struggling to keep from falling to the floor. She then collapsed, her pulse was unobtainable and she died in a matter of minutes.

The significant autopsy findings were marked congestion of the trachea and bronchi, with a thick gruel-like substance along the trachea, bronchi and running down into the smaller bronchioles.

I believe Dr. Feldman's calling attention to the possible adverse effects of ataractic drugs on the respiratory system is important for all physicians who employ such therapy.

IRVING J. FARBER, M.D.,
Forest Hills, New York.

WAGNER-JAUREGG

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: Being a pupil and great admirer of Wagner-Jauregg, I was very pleased that you commemorated his 100th birthday (Am. J. Psychiat., June 1957). I would like to add a few facts, interesting especially for Americans.

It was Wagner-Jauregg who introduced postgraduate courses for foreign physicians and he is the originator of "The American Medical Association of Vienna" which brought about an important exchange of medical knowledge and culture between both countries.

Wagner-Jauregg was also the first to recognize the significance of radiology and worked actively for the establishment of a

central institute for x-rays. Many of the internationally known founders of radiology, a science whose importance is now more evident than ever, came from this institute.

After Wagner-Jauregg's retirement, Otto Poetzl, a former associate, succeeded him. Another associate, Josef Gerstmann, Wagner-Jauregg's closest collaborator of many years, especially in the field of malariatherapy, lives now in New York.

Wagner-Jauregg's memoir, *Julius Wagner-Jauregg, Lebenserinnerungen* (Reviewed in this JOURNAL July 1952, pp. 73) by L. Schoenbauer and M. Jantsch (Wien: Springer Verlag, 1950), gives an excellent picture of his personality and work.

EDITH KLEMPERER, M.D.
New York City.

ELECTROSHOCK THERAPY

Editor, THE AMERICAN JOURNAL OF PSYCHIATRY:

SIR: I would like to make a few comments in reply to the letters by 1. Edwards and Listwan; 2. Impastato; 3. Marshall, in the July 1957 issue of the JOURNAL.

Referring to our experiences at Pinewood, we have, with our own modifications, followed Impastato's method of a muscle relaxant plus a subconvulsive shock prior to the convulsive treatment. Our equipment is

Reiter's unidirectional machine, Model RC-47D and Reiter's Mol-ac II machine with anectine the muscle relaxant. As a routine we prescribe in new cases 5 mgms. of anectine, increasing the dosage per treatment as rapidly as we feel necessary until the desired effect is attained. Approximately 10 seconds after the injection, a subconvulsive shock is administered and this is followed, in about 15 to 30 seconds, with the convulsive shock. Occasionally this latter period must be

lengthened in order to obtain the desired effect, but in the majority of cases the shorter period is effective.

We have not found it necessary to prescribe sodium amytal prior to the treatment procedure. Pinewood is a private hospital where treatments are given in the patients' rooms and pre-treatment anxiety is comparatively uncommon instead of being the rule.

We do not use oxygen before the convulsive stage, nor do we use it following treatment in the majority of cases. It has been found that under ordinary circumstances respiration begins fairly promptly after the treatment. In any group of patients however, there are always some who require oxygen to prevent anoxia. On the whole, respiration is delayed as frequently with intravenous sodium pentothal as with anectine.

Our use of intravenous pentothal for the purpose of eliminating anxiety has been practically eliminated. It has been found that in addition to anectine being much simpler to inject (due to the smaller amount

of the drug), some anesthesia is produced, or appears to be, and the patient lies quietly and is seemingly unaware of the situation. Shortly however, the drug begins to cause restlessness and at this point the subconvulsive treatment is administered. This subconvulsive treatment definitely anesthetizes the patient certainly as effectively as the pentothal and in addition it creates a post-treatment amnesia. Our contention is that it is not at all necessary to use a chemical anesthetic, or that legal hazards or cheapness are factors in the use of subconvulsive treatment. In addition to being effective and simpler, it appears to be less dangerous than the use of pentothal, which occasionally causes delayed respiration and also seems to lessen the effect of the shock treatment.

To reiterate, it is our opinion that subconvulsive treatment is a safe, satisfactory and adequate anesthetic in electroshock therapy.

WALTER A. THOMPSON, M. D.,
Clinical Director Pinewood Hospital,
Katonah, New York.

SELF-DISCIPLINE

Mistakes, misunderstandings, obstructions, which come in vexatious opposition to one's views, are always to be taken for just what they are—namely, natural phenomena of life, which represent one of its sides, and that the shady one. In overcoming them with dignity, your mind has to exercise, to train, to enlighten itself; and your character to gain force, endurance, and the necessary hardness. . . . Never to relax in putting your magnanimity to the proof; never to relax in logical separation of what is great and essential from what is trivial and of no moment, never to relax in keeping yourself up to a high standard in the determination, daily renewed, to be consistent, patient, courageous.

—BARON STOCKMAR TO PRINCE ALBERT
(In Lytton Strachey: Queen Victoria)

COMMENT

IDEA AND ACT

From college days comes the recollection that in elementary courses in psychology we learned something about how a sense impression, energizing a neurone circuit, leads to a motor response. The process could be represented graphically. It was a picture of how an idea may spring into action. We learned also that the response might not be immediate; it might be long delayed, germinating in the mind as an idea—an image of the act—until eventually it ended as the act itself. The motor response might, of course, never take place if there were strong enough counter impulses to inhibit it; but if the climate of the mind were favorable, and if the sensory stimuli of the spoken or written word were vigorously reiterated, the motor response, if not indeed probable, at least could not be discounted. It might partake of the nature of a conditioned reflex. Thus it could be shown that, with certain exceptions which need not engage us here, before an act took place there would normally be in consciousness an idea of that act.

Later on, when we gained some acquaintance with criminology, we learned about the *mens rea*. This *mens rea* was just the old germinal idea that elementary psychology taught, only this time it was a wrongful or criminal idea. And if a person who had committed a crime was to be held accountable and punished, then it must be shown that the antecedent *mens rea* was there. If it was held that there was no *mens rea*, we would have one of those exceptions mentioned above and the accused would be adjudged not guilty of a criminal act.

In any case, lawful or unlawful, the thesis is that an overt act is the terminal fact in a causal sequence, and that in general the act follows upon and is a consequence of the idea, which was a mental image of the act.

It seems to follow that *mens rea*, however it germinates, is a dangerous thing, but that when it is specifically implanted in the mind by indoctrination and as part of a credo that has the nature of a religion, its threat be-

comes ominous. The teaching of Communism is fairly well known, and there are examples enough over there of the idea-action sequence.

In 1940 the Congress of the United States passed the Alien Registration Act, commonly known as the Smith Act. This act has not been repealed. One of the clauses makes it a crime to "advocate overthrowing any government in the United States by force or violence." In 1949, after a jury trial that lasted 9 months, 11 leaders of the Communist party were convicted of conspiracy to advocate overthrow of the Government by force and were sentenced to prison terms and fines. In 1951 the United States Supreme Court ruled that the convictions were valid and that the Smith Act as applied in the case was constitutional. The vote was 6 to 2.

During the interval since, 145 Communists have been indicted and 89 have been convicted under the Smith Act. Fourteen of these carried their cases to the Supreme Court, and in June 1957 the Court set aside their convictions. The ruling was based on arguments that the majority of the Justices conceded were "often subtle and difficult to grasp." Justice Clark dissented from the decision, stating that the distinctions were too "subtle and difficult" for him to grasp.

In its 1957 decision the Supreme Court did not repudiate the Smith Act but in interpreting it performed an extraordinary feat of psychological acrobatics. This feat consisted of a gossamer-fine distinction between "advocacy of abstract doctrine" and "advocacy directed at promoting unlawful action." According to this dialectic, "teaching of forcible overthrow as an abstract principle, divorced from any effort to instigate action to that end" is quite permissible, and presumably the High Court is prepared to defend such teaching. And so we come back to our original question—that of the relations of the idea (whether qualified as "ab-

stract" or not) to the act, and of the *mens sana* which is harmless to the *mens rea* which is criminal. Who is capable of drawing the fine distinction between the state of mind of one who teaches the commission of a crime

as a mere "abstract principle" which is declared to be lawful and the state of mind of one who commits that crime or instigates its commission? The argument is indeed "subtle and difficult to grasp."

INFORMATION VALUES

Psychiatry is presently more in the news than ever before. This may not mean much since there are other fields of knowledge as well as of ignorance about which newspapers are printing much more than the somewhat neutral bystander could expect and digest. There are now many more people who have learned to read than in times past, and there are radio and TV.

As regards psychiatry a few facts stand out which I want to mention. The old hostility to psychiatry is still alive. Psychiatric institutions and psychiatrists are still considered with outspoken prejudice. There is the notion that patients once taken care of by psychiatrists are more or less "goners." Whoever is known to be in psychiatric treatment is adjudged crazy by certain groups of our society; the compliment is occasionally extended to the therapist, for "who, after all, would deal with crazy people unless he were crazy himself?"

At the same time within psychiatry great efforts are made to train more and more psychiatrists, and, of course, to train them well. It is figured out statistically that the ratio of psychiatrists to population is unsatisfactory. A continued increase of persons needing psychiatric treatment is expected and predicted.

Streams of literature coming from two sources unite in the attempt to enlighten people. This is the popular literature in which the public is told all manner of things concerning psychiatric disturbances and abnormalities. The two sources are the professional (psychiatric) and the lay writers who in the make-up of their articles and books show unmistakable similarities, e.g., the readiness to impress their readers with sensational material connected with the expectation to appear on the best seller list. It is impossible to find out which of the two sources is doing more harm. Only too often the writers do not show common sense; Dr. Alvarez,

a physician of undeniable common sense has repeatedly made remarks with sarcastic humor about this deplorable lack. (This observation does not imply that I am particularly enthusiastic about Dr. Alvarez's column.)

It is easy to pick out a particular school of medical psychology and make it responsible for the whole dilemma. If such schools were not gratifying certain needs they could not have become so successful as they still are. And, logically, if those sensational products in printer's ink were not greedily "bought" by a rather large portion of the social group, much of that ink would be spared.

We read about successes in psychotherapy, physical therapy, and research before the pertinent data have been collected and evaluated. A goodly number of non-psychiatrists pretend and probably believe that they know much better than the psychiatrists. The very reserve and reluctance of the professionals who are not willing to spill unripe beans gives those outsiders a welcome start.

All this would be irrelevant and would best be ignored if there were not all those hopes raised that cannot be fulfilled. Patients come or are brought to psychiatric offices and hospitals not only with ready made diagnoses, but with the request for a certain type of therapy, e.g., shock treatment, concerning which they or/and their relatives have been informed through the kind of literature under consideration here. The Miltown epidemic, incidentally, was a case in point of inept, unprofessional information and its abuse.

Can anything be done about this situation? One may think that the agencies devoted to world, national and municipal mental health and mental hygiene have the task to gather and to distribute valid information. However, who decides what information was or is or will be valid? It is obvious that these agencies ought to receive their information from

reliable psychiatrists and psychiatric institutions. Who decides which psychiatrists and which psychiatric institutions are reliable? Who can hinder an all too eager young doctor from talking about "developments" as though the aims of pertinent labors were already reached?

I shall not attempt to answer these questions. But I shall make one recommendation. It is easy to talk about "ethics"; it is not quite so easy to keep a host of professional workers within ethical bounds. It is possible,

though, to remind members of the group of their moral obligations, and it is desirable and feasible to warn them to be utterly cautious in their pronouncements. What a blessing it would be if the publication of books which are neither bona fide literary works nor scientific treatises were stopped! It appears to me that this would be apt to do something to de-ridicule contemporary psychiatrists and psychiatry.

EUGEN KAHN, M. D.,
Galveston, Tex.

CALIFORNIA MENTAL HEALTH SERVICES

The California Department of Mental Hygiene reports the release rate of patients from the state hospitals increased by 31% during the decade 1947-1956. This increase was attributed to several factors including: an increase in the ratio of hospital workers to patients; an increase in professional staff trained in psychiatric therapeutic techniques; improved material facilities designed specifically to provide treatment, not only of the acutely mentally ill patient, but also of those who may be physically ill or handicapped. Other contributing factors include the application of the more recent advances in drug therapy, an increased public awareness of the needs of patients when released to communities, and corresponding public co-operation.

The admission rate per 100,000 of the population declined from 135 in 1953 to 129 in 1956 although the total state population increased 13% in that period. During that same four-year period the resident hospital population rate per 100,000 of the general population declined from 297 in 1953 to 275 in 1956. Coupling this trend with that of the currently projected new facilities, the

department expects that the present overcrowding of the state hospitals will be brought to an end by the fiscal year 1960-61.

The department's budget for the fiscal year 1957-58 totals \$110 million. Of this amount, \$92.5 million includes a substantial increase in the level of personal services for existing hospitals and provides for the operation of newly completed facilities; expansion of family care services; continued planned research; and the establishment of additional outpatient care, including a "day-night" care program. The budget also projects \$18.5 million for the development of additional hospital facilities.

The significance of this comment may be better appreciated when it is realized that 16 years ago the California state hospitals were custodial institutions, without special facilities or personnel for the intensive treatment of the acutely mentally ill. No community mental health facilities existed and no organized effort to train or teach personnel existed west of the Rockies.

W. L. T.

Convictions are more dangerous enemies of truth than lies.

—NIETZSCHE

NEWS AND NOTES

PUBLIC HEALTH MISSION TO RUSSIA.— Leroy E. Burney, Surgeon General of the Public Health Service, reports that 5 United States public health physicians departed August 13 on a 4-week exchange mission to the USSR. Chairman of the mission is Dr. Thomas Parran, Dean, Graduate School of Public Health, University of Pittsburgh, and a former Surgeon General of the Public Health Service. This mission was arranged by the Public Health Service, in co-operation with the U. S. Department of State. The visit will provide opportunities for closer contacts between public health and medical leaders of the 2 nations, and will facilitate the exchange of technical information in health fields.

The American physicians will visit cities and villages in 5 of the 15 republics of the USSR in Europe and Asia. They will visit the Union Ministry of Health, city health departments, hospitals, dispensaries, industrial medical services, research institutes, and medical schools. A reciprocal Soviet Union public health mission will visit the United States in October.

POSTGRADUATE CENTER FOR PSYCHOTHERAPY.—In October 1957 the Postgraduate Center for Psychotherapy (218 E. 70th St., New York City) will initiate a series of International Seminars in the field of mental health by presenting Dr. W. Grey Walter, internationally renowned British neurophysiologist. Speaking on "Brain and Behavior," Dr. Grey Walter will address an open meeting at the New York Academy of Medicine at 8:00 p.m. on October 23, 1957. He will also lead two other seminars, on October 20 and 31; the subjects will be "The Physiology of Personality" and "The Cybernetic Approach to Mentality and Society." At the third meeting he will demonstrate his "electronic turtle," one of the models he designed and built for the study of nerve mechanisms.

W. Grey Walter, one of the pioneers in the development of electroencephalography,

is the inventor of a number of electronic models of nerve mechanisms, including the Conditioned Reflex Analogue which responds to an association of ideas or stimuli by a process of apparent anticipation.

DEATH OF DR. LOWREY.—With great regret we have to announce the death of our associate editor, Lawson G. Lowrey, on August 16, 1957. His death was due to a coronary occlusion. Dr. Lowrey had been a member of the editorial board since 1951 and brought to us the benefit of his considerable previous editorial experience. His loyal co-operation has been invaluable. A memorial notice and biographical sketch will appear in a later issue of the JOURNAL.

REGIONAL RESEARCH CONFERENCE, MONTREAL.—The American Psychiatric Association will hold its 6th Regional Research Conference in Montreal under the auspices of McGill University on Friday and Saturday, November 8 and 9, 1957. Final details of the program will be announced later. Invitations are being sent to all psychiatrists in Ontario, Quebec and the Maritime Provinces, and in northern New York State and northern New England.

Those wishing to submit papers or to suggest topics for discussion should communicate promptly with Dr. D. Ewen Cameron, chairman of the department of psychiatry, McGill University.

Three half-day sessions will be devoted to papers and the fourth to audio-visual presentations. The general topics at present under discussion are: 1. communications; 2. remembering; 3. effects of repetition of verbal signals on behavior; 4. object relations; 5. time and timing as pathogenic agents.

INFORMATION FOR RELATIVES OF HOSPITAL PATIENTS.—A booklet for relatives and friends of patients entering the state mental hospitals has been published by the N. Y. State Department of Mental Hygiene.

Designed to reassure the anxious family, the booklet explains what happens to the patient in the hospital and points out the role of the relative. Necessary rules and regulations and the reasons for them are discussed. The theme of the text is that after a patient is admitted, the hospital and the family must work together toward his recovery.

INTERNATIONAL ASSOCIATION OF APPLIED PSYCHOLOGY.—The International Association will hold its 13th Congress in Rome, April 9-14, 1958. Plenary sessions will deal with psychology in the training of managers, physicians, teachers and judges.

Sections of the Congress will be devoted to problems of industrial psychology and vocational guidance; medical psychology; educational psychology and legal psychology.

For further information, write the Secretary-General, Prof. Luigi Meschieri, 41, Rue Gay-Laussac (5^e), Paris, France.

THE AMERICAN PSYCHOSOMATIC SOCIETY.—The 15th annual meeting of the American Psychosomatic Society will be held in Cincinnati, on Saturday and Sunday, March 29 and 30, 1958.

The Program Committee would like to receive titles and abstracts of papers for consideration for the program, no later than November 15, 1957. The time allotted for presentation of each paper is 20 minutes.

Abstracts in octuplicate should be sent to the Chairman of the Program Committee, Dr. Theodore Lidz, 551 Madison Ave., New York 22, N. Y.

NEW YORK STATE LEGISLATION CONCERNING MENTAL RETARDATION.—The Report of the New York State Joint Legislative Committee on Mental Retardation, 1957, describes legislation introduced at the request of the committee and passed in 1956. The 7 laws thus passed deal with inequities arising from liability for payment of care in mental hospitals; financial aid for Cooperative Boards; obtaining all facts concerning mentally retarded children; permitting private organizations to conduct classes in public schools; deleting the mandated 3-year age limit for classes; continuous study of the

incidence of mental retardation; greater state financial aid to the mentally retarded; the establishment of a single basic program for state aid and the establishment of 2 demonstration centers for the purposes of case finding, diagnosis and parent counseling.

Some of the recommendations of the committee for 1957 concern the obtaining of state aid to employ psychologists; the establishment of a separate division within the Department of Hygiene for an administrative program for the mentally retarded; establishment of a policy of separate facilities for mentally retarded delinquents; appropriate classes to be set up by boards of education for the retarded between the ages of 5 and 21; mandatory transportation; and scholarships for the training of teachers for mentally retarded children.

PROBLEMS OF AGING.—A pioneer Regional Center for Research on Aging is to be established at Duke University, Durham, N. C.

First of its kind in the nation, the center will be supported in part by a U. S. Public Health Service grant expected to total more than \$1,500,000 over a 5-year period. The center will serve as a pilot project in the Southeast and its success may determine whether or not similar undertakings will be launched in other regions with support from the National Institutes of Health in the USPHS.

Specific aims of the center, which is expected to be in operation within the next 18 months, include encouragement and support of research into the phenomenon and health problems of aging; training of research investigators; and development of a source of scientific knowledge in this field for government as well as for private groups.

CONNECTICUT POSTGRADUATE SEMINAR IN PSYCHIATRY AND NEUROLOGY.—The 11th Postgraduate Seminar will extend from September 18, 1957, through April 16, 1958.

From September 23 through December 6, 1957, sessions in clinical neurology, neuro-roentgenology, electroencephalography, neuroanatomy, neurophysiology and neuropathology will be held on Mondays and Wednesdays from 3:00 to 9:00 p.m., at the

Yale University School of Medicine, New Haven, Conn. On November 27 and December 2, 1957, four sessions in clinical psychology will be held from 4:00 to 9:00 p.m., also at the Yale University School of Medicine.

From January 6 through March 3, 1958 (Mondays), from 3:00 to 8:45 p.m., sessions in general psychiatry, psychosomatic medicine, geriatrics, and psychiatry and law will be held at the Connecticut State Hospital in Middletown.

From January 8 through March 5 (Wednesdays), courses in child psychiatry and pediatric neurology will be given at the Yale University School of Medicine from 3:00 to 8:30 p.m.

There is no fee for the above courses.

Copies of the program may be obtained from the Office of the Assistant Dean for Postgraduate Medical Education, Yale University School of Medicine, 333 Cedar Street, New Haven, Conn.

EASTERN PSYCHIATRIC RESEARCH ASSOCIATION PAPERS.—Reports of papers read at the 1st annual meeting of the Eastern Psychiatric Research Association in October 1956 are presented in a monograph supplement to *Diseases of the Nervous System* for July 1957. It is a welcome service on the part of Editor Harris to have made this material available in this way. The supplement gives an introductory account of the origin and organization of the Eastern Psychiatric Research Association and presents photos of its first officers: president, Dr. David J. Impastato; vice-president, Dr. Leo Alexander; secretary-treasurer, Dr. Theodore R. Robie; and councilors, Drs. Joseph Epstein, Emerich Friedland, William L. Holt, Jr., and Harry R. Lang.

Of especial value is a complete report with detailed table by President Impastato of fatalities in EST, based on the studies of 214 fatalities reported in the literature and 40 fatalities previously unpublished.

This supplement includes also reports of papers read at a seminar on EST at Kings Park State Hospital in October 1957.

A roster of members of the Eastern Psy-

chiatric Research Association, numbering 120, is also included.

DR. TYHURST GOES TO THE UNIVERSITY OF BRITISH COLUMBIA.—From the Allen Memorial Institute of Psychiatry, McGill University, comes the announcement that Dr. J. S. Tyhurst, professor of psychiatry at McGill, has been appointed professor and chairman at the department of psychiatry at the University of British Columbia, and head of the department of psychiatry at Vancouver General Hospital.

DR. SLOANE TO HEAD PSYCHIATRY AT QUEENS UNIVERSITY.—Dr. R. B. Sloane, lecturer at McGill University and assistant psychiatrist Royal Victoria Hospital, Montreal, has been appointed professor and chairman of the department of psychiatry at Queens University, Kingston, Ontario.

SALMON LECTURES 1957.—The Salmon Committee on Psychiatry and Mental Hygiene announces that this year's Thomas William Salmon Lectures will be given by Dr. David McK. Rioch, Director of the Division of Neuropsychiatry at the Walter Reed Army Institute of Research in Washington, D. C.

Dr. Rioch will speak on "Research in Psychiatry: Certain Problems and Developments in Multi-Disciplinary Studies," and the talks will be given at 4:30 and 8:30 p.m. on Thursday, November 21, 1957 at Hosack Hall of the New York Academy of Medicine.

EASTERN PSYCHIATRIC RESEARCH ASSOCIATION OFFICERS, 1957.—At its annual meeting in June 1957, the Association elected the following officers for the forthcoming year: president: Dr. Leo Alexander; president-elect: Dr. Theodore H. Robie; 1st vice-president: Dr. William L. Holt, Jr.; 2nd vice-president: Dr. Charles Buckman; secretary-treasurer: Dr. David J. Impastato; asst. secretary-treasurer: Dr. Lawrence H. Gahagan; councilors (for 2 years): Dr. William Furst and Dr. Pasquale Lotesta; councilors (for 3 years): Dr. Nicholas Locascio and Dr. Evelyn Ivey.

BOOK REVIEWS

DIE BEURTEILUNG DER ZURECHNUNGSFÄHIGKEIT.
Ein Vortrag. (Dritte Auflage.) By *Kurt Schneider*. (Stuttgart: Georg Thieme Verlag, 1956.)

In the first part of this concise and lucid booklet, Schneider presents a short outline of his psychiatric nosological system developed largely on the basis of Karl Jaspers' psychopathology. Abnormal behaviour is either a sign of disease or an expression of abnormal mental variation. The concept "disease" is understood in a purely medical sense. It comprises the known diseases like general paresis or senile brain disease as well as postulated diseases where the clinical picture indicates the presence of a disease process although the latter is still not proved as in schizophrenia and manic-depressive psychosis. "Abnormal variations" are essentially different from diseases in that they are purely quantitative deviations from the average. No sharp borderline exists between normality and abnormal variations. In the intellectual field only the negative variations are of psychiatric importance. Clinically, they appear as congenital mental deficiencies of moderate degree whereas the severer forms are usually a sign of "disease." Other abnormal variations are abnormal vital drives, abnormal (psychopathic) personalities and abnormal reactions which comprise also the neurotic reactions.

This nosological system forms the basis for the application of Article 51 of the German Criminal Code in psychiatric cases. This article states that a punishable act has not taken place if the perpetrator at the time of the crime did not have insight into the nature of the crime or the ability to act according to this insight; either because of clouded consciousness, morbid impairment of his reasoning, or mental deficiency. If insight or the ability to act according to it was only diminished the penalty may be diminished as with an attempted crime.

According to Schneider the benefit of Article 51 should be applied in all cases of psychiatric disease, known or postulated, and in those cases of Group 2 of his classification which lead to impairment of consciousness or in cases of mental deficiency. It will usually suffice to make the clinical diagnosis because the presence of one or the other disease entity automatically implies one of the three conditions mentioned in Article 51.

The most interesting part of Schneider's booklet, however, is his discussion of the problem whether and how far the psychiatric expert is able to express an opinion regarding the accused's insight into the criminal nature of the act and his ability to act accordingly. Consequently, Schneider holds that these questions are unanswerable and remain so in a court of law. The reason is that Article 51 is based on an outdated psychology which divides any action into a rational part during which

the acting subject deliberates on the intended act, and into a phase of decision, when he decides which course to follow. As, however, our actions result from the interplay of drives, some of them unconscious, voluntary decisions between possible courses of actions are extremely rare. Moreover, it seems impossible to determine whether in a given situation of temptation ethical insight actually appeared. The time factor is also of importance, as in criminal deeds of a more complicated nature more time may elapse and more opportunity to achieve insight. As far as the ability to act according to insight is concerned, the situation for the expert is still more difficult. Even the assumption of a "free will" as the basis of any criminal code does not help because it is impossible to state whether an individual at a given moment could make use of it. In short what the expert does is to conclude on clinical diagnostic grounds whether Article 51 is applicable or not.

Although Schneider's booklet deals only with the German Criminal Code its content makes worthwhile reading for everybody interested in forensic psychiatry.

ASPECTS DE LA PSYCHIATRIE MODERNE. By *Jean Delay*. (Paris: Presses Universitaires de France, 1953.)

The first part consists of the traditional inaugural address delivered by the author in 1947 when he was appointed Chief of the Clinic of Mental Diseases of the Faculty of Medicine. It begins with an expression of homage to his predecessor and teacher Levy-Valensi, whom the Nazis killed in a gas chamber. He pays tribute to his various teachers and guides, whose names represent a veritable Who's Who in French medicine—Pierre Janet, Pichon, Laignel-Lavastine, George Dumas and others.

He narrates the development of the physical sciences in service of psychiatry such as pneumo- and electro-encephalography, chronaximetrics, etc. The chronaximetrics is a French discovery and was developed by Lapique and Bourguignon. Psychochemistry studied the correlation of mental activity with hormones vitamins. The greatest progress the biological methods made in psychiatry are represented by shock therapy. This method does not react on the cause of mental disorder but on its mechanism. It appears to the author that the action of electroshock, being both physiologic and psychologic, proves that its effect is not only on the encephalon as was once thought but on the functional correlations between the diencephalon and the frontal lobe and more generally between the basis and the cortex of the brain.

The introduction of intelligence and character tests like those of Binet-Stanford or Wechsler-Bellevue, the Minnesota or the Rorschach enable us to make a psychological analysis with the greatest objectivity.

The research in the origin of mental disease cannot limit itself to physical causes but has to consider also moral causes. It was Charcot who was the first to call the attention of the medical profession to the role played by the subconscious in the neuroses and particularly in hysteria, Charcot and not Freud. Freud recognized the great debt he owed to the teachings of the Salpêtrière. He arrived in Paris when 29 years old and had specialized in pure neurology under Meynert without revealing any trace of his future orientation. But he was soon influenced by the Tuesday lectures of Charcot and his demonstrations of hysterics and hypnotic treatments. He even overheard Charcot telling Brouardel: "At the source of such an illness there is always a sexual element." When Freud returned to Vienna and to Breuer, he discovered, while treating a hysterical person, a new approach, quite different from hypnotism: the psychoanalytic.

Delay discusses the two tendencies that characterize the evolution of psychiatry: one looks for physical causes of mental disease and utilizes physiotherapy, the other looks for moral causes and utilizes psychotherapy. If the emotional conditions repeat themselves, an acute disorder becomes chronic. For example: paroxysmal arterial hypertension becomes chronic hypertension, occasional acid hypersecretion from the mucosa of the stomach becomes an ulcer. Functional troubles do not appear any more as a result of a discreet anatomical lesion but as its cause. He describes a visit to New York Hospital where he saw in the clinic of Harold Wolf a patient with a gastric fistula who was subject to crises of paroxysmal anxiety. Harold Wolf who studied according to Cannon the gastric reactions to emotion, observed that when the patient's condition was that of paroxysmal anxiety, the motility and the secretion of gastric acid increased and the small hemorrhages from the mucosa eroded into an ulcer. He demonstrated that an emotion may cause ulceration.

In his opening address at the First World Congress in Psychiatry (Sept. 19, 1950), Delay described the admirable study and classification of mental diseases by the psychiatrists of the 19th century as a class by itself. The introduction of biologic techniques in psychiatry belongs to the last half-century. The first use of lumbar puncture was in the infectious diseases of the brain and meninges. Later it developed into ventricular intervention and the relationships between mental and hydrolic equilibrium. Hypertension or hypotension of the brain were treated by decompression or insufflation. Dandy has shown that the injection, through the lumbar or ventricular regions, of gas or fluids, transparent or opaque to XRay, permits us to learn about certain conditions of the brain.

The biophysicists saw in all the functions of the brain, electrical influences. The "animal spirits" that, according to Descartes, issued from the pineal

gland, were nothing else than the propagation of electrical waves. Adrian, Lapicque and MacCulloch made further contributions to the interpretations.

The author comments further on the various therapeutic methods of Sakel, Meduna, Cerletti, Fiamberti and Lopez Ibor. He discusses the complexity of the psychic and physical reactions that accompany shock. In the observations of Aschner, Camus, Roussy, Claude and Lhermitte.

"Neurosis and Creation" is the title of a Presidential address which Delay delivered in Liège July 25, 1954 at the 52nd Congress of Neurologists & Psychiatrists. He discusses the theories of Lombroso and Nordau that caused hot polemics by the end of the century on the topic of degeneration. André Gide in his essay on Dostoyevsky expressed the idea that the cause of every great moral reform, of all changes of values, is a physiological mystery. He discusses in a new light the mental deviations of authors in modern times.

HIRSCH LOEB GORDON, M. D.,
New York City.

THE CIRCLE OF GUILT. By Fredric Wertham, M. D.
(New York: Rinehart & Co., Inc.; Toronto:
Clarke, Irwin & Co., Ltd., 1957. \$3.00.)

In 1954 Kenneth Chapin, aged 20, killed a 19-year-old baby-sitter and the little boy aged 4 she was guarding. The weapon was a bayonet. The youth had stabbed the girl 38 times and the child 23 times. This was in Massachusetts. No motive for the crime was established. The killer was first sentenced to death, but the sentence was later commuted to life imprisonment.

The Chapin case represents a special type of juvenile crime. The one discussed in this book is of another type—a teen-age gang homicide in New York City. A Puerto Rican youth, Frank Santana, aged 17, accompanied by two other members of his gang, all Puerto Ricans, encounters a youth belonging to a hostile gang. Some blustering words and behavior follow. Frank takes a gun from his companion and, whether by design or accident, the gun is discharged and the unfriendly boy is killed.

In court several months later Santana pleaded guilty to second degree murder and there was no trial. For this crime the sentence required by law is 20 years to life. The judge gave him 25 years.

Dr. Wertham had been retained by the defence, with no fee, since the family of the accused was on relief. The purpose of his investigation was to establish all the factors, social, economic, cultural, educational, that might reasonably be assumed to have bearing on the crime, to show what kind of personality Santana had developed, what was the customary content of his mind, what had come to be his standards of conduct, and therefore to indicate if possible whether *mens rea* could be said to have existed at the time of the shooting. All this would have been useful information for the jury in the event that the case had come to trial. There were background conditions, Santana's almost daily sessions at crime movies, his daily diet of horror comics—"creeps" was the common term

for these books. Santana had collected as many as two or three hundred of these creeps. No other literature interested him. Wertham calculated that in the 4 years that Santana had been in continental United States "in the comic books that he had read and in the movies that he had attended, he had seen at least 22,000 homicides." He quotes George H. Pampfrey who said, "One thing is certain: children fed on a regular diet of horrors and brutal crimes will gradually lose their sense of what is right and wrong."

An especially important chapter in this book is one dealing with the Island of Puerto Rico where Santana was born, its history and development and the living conditions there before and after the Spanish-American War when the Island was annexed to the United States (1898). Conditions existing in Puerto Rico during the twentieth century, as described by John Gunther and others, are not flattering to the United States. These conditions throw light on the considerable migration of Puerto Ricans to the mainland, as they have a right to do being citizens of the U.S.A., but where they are met with unfavorable prejudice and discrimination and a common view that they represent a substandard group. These circumstances do not promote integration but help to explain why the ratio of delinquency and crime among Puerto Rican minors on the mainland is so much higher than in their island home.

Because there was no trial Wertham did not have the opportunity to present before a jury the data he had collected and the conclusions he had drawn therefrom, and so he decided "to write them for a larger jury" in this revealing volume.

C.B.F.

HEARING THERAPY FOR CHILDREN. By *Alice Streng and others.* (New York: Grune & Stratton, 1955. \$6.75.)

In the preface the authors claim that they have produced the first book to contain in one volume the special skills and knowledge needed by members of certain professional groups who work with hearing handicapped children. The groups mentioned are the physician and five groups of lay people.

The hopeful reader notes with approbation the titles and sequence of the chapters and at the end of each of the latter a list of papers by many distinguished writers and workers.

The field covered by the book is so broad that no one reader could claim such mastery as to be able to justly criticise every detail. The writer of this review has devoted many years to children with impaired hearing and deaf children and knows many of the authors whose works are referred to and believes that the book fails to achieve its aims.

This book is ostensibly written regarding the needs of children—and children require very careful consideration. Only older children who are thoroughly healthy, well disciplined, and of above average intelligence can be subjected to the tests

and the treatments suitable for adults. Even such children require unusual gentleness and patience and these qualities must be joined with unusual skill. A child is very able to detect lack of these qualities in its otologist and when it does, the examining, the testing and the decisions made are apt to be very wrong. The younger the child the greater the difficulties.

Every page of a book with this title should be permeated with this point of view. A number of fundamental misconceptions greatly impair the value of its message.

It is true that the antibiotics, when properly used, diminish the severity of upper respiratory infections so that mastoid surgery is much less frequently required and incision of eardrums is fortunately uncommon. Earache should be treated promptly and often is—but it is still very common and earache often means otitis media, and every otitis media carries with it the threat of impaired hearing. The lesson for the lay groups should be insistence on adequate and persistent treatment of every case of earache by the physician. Prevention should be the keynote.

It is implied that a pure-tone audiogram has the same meaning from coast to coast and that the meaning is very valuable. But it has been demonstrated unquestionably that audiograms on the same patient obtained under different environmental conditions, and by different examiners can be amazingly dissimilar. An audiogram is nothing more than a record of how a patient responded on a certain date to a certain technique under certain conditions. When repeated at a later date comparison of the two records has no value unless the technique and conditions were exactly the same as those of the first test. No diagnosis can be made from an audiogram alone. And finally—pure-tone audiograms on little children can be extraordinarily full of errors.

Great stress is laid on "interpreting the audiogram." Some technicians can be taught to administer some of the tests but from what has just been said such technicians should *never* interpret them. And yet this book tells them how to do so.

The bibliographies in some instances contain references which to judge from the text of the preceding chapter have not been read or if they have been read have been misunderstood.

The index is far too short and it is irritatingly inaccurate.

To give a complete account of the failings of this volume would take a great deal of space. It is doubtful whether any chapter except the one, "Hearing Losses and their Medical Treatment," will satisfy any reader of moderate ability in an acquaintance with otology. It contains a vast amount of information and details of many skills which the lay groups for which it is written do not require and cannot understand.

A DOCTOR'S BOOK OF THE HOURS. By *Merrill Moore*. (Springfield, Ill.: Charles C. Thomas Co., 1955, pp. 397. \$6.00.)

Merrill Moore speaks of having written in the neighborhood of one hundred thousand sonnets. The question still remains: a *tour de force* or a dissipated talent? His recent volume, *A Doctor's Book of Hours*, presumably the output of one year, runs to 397 pages, the equivalent in quantity to the collected works of many major poets. It does not lend itself to classification and refuses to fit neatly into this category or that. Call it poetry and immediately it springs a leak and drains away into journalism; but the dilemma remains, for every now and then a live poem jumps from the page and, presto, the good reporter becomes a good poet.

The months of the year give titles to the 12 sections of the book; sub-headings include Analysis of Men, Natural History, The Clinic, Public Life etc., and it might seem that every angle of the world we live in, of the inner and outer man, had been explored by this prolific sonneteer. One expects Moore, as psychiatrist and poet, to be a kind of double deity (poets have ever considered themselves divine, and the psychiatrist must perforce play the role of god), yet even in the discerning sketches of people the poems seldom transcend the analyst's couch.

Though *A Doctor's Book of Hours* demands a patient search before it reveals the talent that is, nonetheless, scattered through its pages, the reader whose interest does not lie in consistent poetic merit will find a variety of lively observation and good reporting on a multitude of subjects. Merrill Moore himself describes the poetic process; he would do well to take his own words to heart, and to buy a new and stronger lock for the djinn. Here are his lines:

THE POET OWNS A DJINN, SHUT IN A BOTTLE HE
RUBS OCCASSIONALLY; THE BOTTLE IS HIS MIND

The impulse to write a sonnet is an impulse
To record something that is momentarily
Felt with volatile intensity
Or something that may, over a longer time,
Be felt more deeply, although less intensely
But with a kind of continuity
And earnestness approaching the sublime.

More than that, (this is only the beginning)
Sonnets are virtuous, the opposite
Of sinning; for example when we look
With comprehending eye on Shakespeare's book,
We find a record of great passion there,
Most of which, I suspect, was thinnest air,
Not flesh and blood, because, if it had been
An active passion, in reality,
The poems would *not* be written, and the djinn
Would have escaped the bottle;

as it is,

His strength lies in this fact: he is confined,
His power is locked in the poetic mind.

ANNE WILKINSON,
Toronto, Canada.

AMERICAN LITERATURE AND THE DREAM. By *Frederic I. Carpenter*. (New York: Philosophical Library, Inc., 1955, pp. 220. \$4.75.)

"The American Dream" began long before the Revolutionary War. It started in Western Europe and the British Isles. It was very simple in its origin and it meant only one thing—a fuller, richer, and better life for all. It was not a revolutionary concept and had nothing whatsoever to do with any later "socialist" or even later "communist" ideas. It did share something of the qualities of Sir Thomas More's "Utopia" and possibly it got something from Plato's "ideal" for a republic.

In this book the author makes remarkable selections from American literature beginning with Emerson and Bronson Alcott and brings the idea up to date including stops at many way-stations. Walt Whitman would be amazed if he were living to see his casual thoughts so sharply emphasized. Melville, now so popular as the portrayer of Moby Dick, is allowed to contribute a small donation.

In Part 4 of this book more recent thinkers are grouped under the heading of "pragmatists" and even Eugene O'Neill is given some credit. The author has objectively harvested a very wide field, but he has sifted his material down to "big" names and the way they deal with "big" ideas for good and for evil. He treats Robinson Jeffers in an interesting way, also Thomas Wolfe, John Steinbeck, William Saroyan and Ernest Hemingway. I wish he had also analyzed John Crowe Ransom and Robert Penn Warren, who have much to say about the general topics of this book. It is very provocative writing but not always conclusive. The general method of the author is eclectic and this book will appeal to the general reader who has begun to think about that most basic of all ideas, what is good and what is not good, as it applies to the major literary figures who have written since the American states became united.

MERRILL MOORE, M.D.,
Boston, Mass.

THE DIRECTION OF HUMAN DEVELOPMENT: BIOLOGICAL AND SOCIAL BASES. By *M. F. Ashley Montagu* (New York: Harper & Brothers, 1955, \$5.00.)

We are in the midst of a surge of interest in the meaning of personality development, as it has become increasingly obvious that this topic has a unifying and profound influence on all the aspects of the behavioral sciences. Professor Ashley Montagu joins this movement by presenting his synthesis of the process of human socialization.

This volume had its inception in the sociology classrooms of Harvard University in 1945, and was nurtured to birth through teaching at other universities. (A preliminary precipitate, entitled *On Being Human*, was published in 1950 by Henry Schuman.) Dr. Montagu has brought together the research consequences of hundreds of studies, all properly notated, and has presented them and his conclusions in a highly readable manner. As he

wanted to reach as wide an audience as possible, he points out that he has omitted many pertinent references.

He begins his presentation with a discussion of the biological basis of co-operation. Much evidence is marshalled to illustrate that even very simple biologic life is interdependent, and that co-operation is a more fundamental rule than the blood-tinged struggle in nature suggested by Darwin. A chapter summarizing the structure and function of the nervous system is followed by one which points out that the expression of heredity is a function of the organic potentialities and the environment. Prenatal development, and influences thereon, are discussed along with the meaning and significance of birth and its trauma. Motivations are divided into basic needs which are closely related to the organic processes of the body, and acquired needs. It is shown that even the vital basic needs become affected by cultural demands, which in turn most significantly determine the vast number and varied acquired needs. The last half of this volume is devoted to variations on the themes of dependency, interdependency and love. The author proclaims the essential goodness of Man, the fallacy of individuality, the importance of early experience, particularly as characterized by love, and the devastating results of a deprivation of love. In his last chapter, he attempts to define the various functions of love. He concludes with a fervent plea that the primary goal of education be the skills of human relations. An appendix makes possible a discussion of learning theory and how it may further our understanding of human development.

This is a good book and a sound one. It represents the best of the current trend to broaden the realization of the importance of interpersonal and cultural influences on personality function and development. With its emphasis on co-operation and love, it may seem to many people that it overlooks the potential aggressivity and destructiveness of Man, whether inborn or learned. It should have a wide audience. The intelligent layman will find it stimulating and instructive, as will the students

of the various social sciences. For the student of medicine, it will be more useful as a reference work than as a suitable text on personality development, because it deals more with the socializing forces than what happens to the person throughout life.

ERIC T. CARLSON, M. D.,
New York Hospital—Cornell
University Medical College.

SOCIAL PROBLEM OF MENTAL DEFICIENCY. By N. O'Connor and J. Tizard. (London & New York: Pergamon Press, 1956. \$5.00.)

This book is an excellent addition to the literature dealing with the problems of the mentally retarded, and particularly, with the problem of the employability of this group. The volume deals with the general care and treatment of the mentally retarded, particularly, in a British scene.

The authors present a detailed psychological study of the high grade defective as a social problem. There is an excellent review of the literature of psychological research and the authors also offer results of their own research in the direction of types and occupations which the feeble minded can be trained to do, and the predictability of success. The outlook on the whole is an optimistic one with emphasis being laid on the necessity of psychological and workshop investigation when arranging for a program of employment placement.

The first three chapters deal with the historical background of the problem of mental deficiency and detail the services for this group in Britain. The ensuing chapters cover studies of training and occupation placement of high grade defectives and investigations into the prediction of occupational success.

On the whole this small volume will be welcomed by professional workers in the field of mental deficiency and will prove a worthwhile guide to those concerned with the rehabilitation of the feeble minded.

Smith Falls, Canada.

SCIENCE

Science is nothing but trained and organized common sense, differing from the latter only as a veteran may differ from a raw recruit: and its methods differ from those of common sense only as far as the guardsman's cut and thrust differ from the manner in which a savage wields his club.

—THOMAS HENRY HUXLEY

AN ENGLISH VIEW OF AMERICAN PSYCHIATRY

MICHAEL SHEPHERD, D. M.^{1, 2}

"It has been difficult," said Dr. Whitehorn in his 1951 Presidential Address to The American Psychiatric Association, "for many European psychiatrists to understand the American situation(25)." He could not have meant to imply that they lack interest in the subject. On the contrary, during the present century the growth and influence of American psychiatry have so increased that to psychiatrists elsewhere a visit to North America has come to constitute an almost indispensable part of their post-graduate education. For financial rather than medical reasons it is unfortunately an experience which has been enjoyed by only a small minority, and without this opportunity the opinions of the European psychiatrist must depend on the conflicting reports of his more fortunate colleagues and on the torrent of American publications. Accustomed to a more centralised tradition of medical training and research, usually with the university clinic in the foreground, he is hard put to it to understand the many, diverse and possibly unfamiliar institutional forces—State supported institutes as well as university centres, federal agencies like the United States Public Health Services, voluntary organisations like the National Association for Mental Health, private hospitals and clinics and the great foundations—which influence the form and direction of American psychiatry to-day. Perhaps it is inevitable that many European psychiatrists, seeking for some uniformity amid seeming chaos, have tended to heed only the most clamant of many voices and have assumed, again in Dr. Whitehorn's words, that "... the psychoanalytic movement has captured American psychiatry."

Among the European schools of psychiatry that of Great Britain has a close traditional link with North America. Between the wars many of the most eminent British psychiatrists made their pilgrimage to the Henry Phipps Clinic, and Adolf Meyer handsomely

acknowledged the contribution of British to American psychiatry in the 14th Maudsley Lecture(20). Describing his impressions of North American psychiatry more than 25 years ago one British professor concluded that "... the future is more secure in America than in any other country(19)." More recently, however, there has been evidence of what another British professor has termed "differences . . . of quantity and tempo" between the psychiatric developments in the two countries(17). Some of these differences have found clear and even sharp expression in publications from both sides of the Atlantic. Dr. Freyhan, however, in his recent sympathetic review of European psychiatry concludes that American psychiatrists are as likely as their European colleagues to be struck by the unfamiliarity of what they find on leaving home(12). Indeed, he goes so far as to stress Professor Bleuler's warning that a breakdown may occur in communication between psychiatrists on the two continents. Such a situation is unknown in other branches of medicine, and it cannot but be deplored. Dr. Freyhan's article also makes it evident that the best in European psychiatry is of interest to American physicians not only by virtue of its intrinsic quality but also because of the light it may reflect on domestic problems. Ample confirmation of his opinion was provided during the year which the author was privileged to spend as a Post-graduate Travelling Fellow in the United States,³ when many of these problems were frequently raised in discussion with American colleagues. The discussions proved invaluable for the purpose of clarifying many obscure aspects of American psychiatry; they also helped make possible the formulation of some general views about it. Incomplete as such views must be, they have been summarised here in the hope that one observer may have been able to see something of interest to the participants.

Many of the misunderstandings which

¹ The Maudsley Hospital, Denmark Hill, London, S. E. 5, England.

² Corresponding Fellow of the A.P.A.

³ Travelling Fellow of the British Postgraduate Medical Federation in the U.S.A., 1955-1956.

have arisen in other countries about American psychiatry spring from a failure to understand the social setting in which the subject is practised (15). It is widely recognised that the content as well as the form of psychiatric practice is moulded by environmental factors. This complex issue can be illustrated by reference to the distribution of psychiatrists working respectively in the public service and in private practice. In England psychiatry, as a branch of medicine, comes within the orbit of the National Health Service; the bulk of the working time of British psychiatric consultants is devoted to salaried service in hospitals or other public institutions and private practice must consequently assume less importance in the majority of cases (1, 21). The efforts of the British Ministry of Health to improve the quality of mental hospitals and to develop them as dynamic centres of community service have been dependent on a supply of well-trained and often highly qualified physicians; to them are due the more liberal use of voluntary legal status, the development of domiciliary consultations, and of out-patient clinics, the experiments with the "open door" and the "therapeutic community," and the emphasis on rehabilitation (7, 16, 18).

Medical care in the United States is organised very differently. Nearly 3,000 of the 7,500 recognised psychiatrists in 1951-52 listed private practice as their major activity (5). By 1954 Davidson has shown that the private practitioners for the first time outnumbered their colleagues in salaried positions; further, one-quarter of them were engaged exclusively in the practice of psychotherapy and were not considered to "... meet the traditional criteria of the practice of medicine (8)." (These figures, of course, take no account of the large number of non-medical psychotherapists practising in the United States, but they have very few counterparts in Great Britain.) It is thus apparent that proportionately fewer American psychiatrists are in salaried public service and their role and functions are correspondingly modified.

A trend of this nature has other implications. Since no form of medical education can be dissociated from the purpose to which it is being put, the organisation of psychi-

atric practice patently exercises a profound influence on psychiatric training. At the present time it is difficult to avoid the impression that to a substantial number of young American psychiatrists several of the major professional incentives—public status, mode of living and financial reward—are associated far more with private practice than with hospital work. From years of experience with a residency training programme in Massachusetts, Barton and Yakovlev reported the "... reluctance of residents to accept even financially attractive appointments in the geographically isolated state hospitals and even in many of the training-wise self-contained institutions (4)." The specialist therefore understandably demands that much of the curriculum should be devoted to psychotherapy and psychodynamic theory. His relationship with his supervisor often constitutes the corner-stone of his instruction (23). Conversely, there is a distaste for the tracts of detailed knowledge dismissed as "descriptive psychiatry"; an antagonism to many of the facts and concepts associated with the study of heredity; a neglect of much biological investigation; and, as Kanner has so strikingly shown, in many centres a biased ignorance of the evolution and the historical roots of modern psychiatry (14).

To an English observer the problems and experiments in psychiatric education in America seem to be of cardinal importance. On the one hand he is impressed by the generous allowance of time afforded to psychiatric instruction in the undergraduate years and by the high status of the subject in many medical schools, even if he takes Professor von Baeyer's estimate of American psychiatry as "... Königin unter den übrigen ärztlichen Disziplinen (24)," to be the comprehensible hyperbole of an admirer. Yet American views on the nature and purpose of psychiatric education are still conflicting and are sometimes uncompromisingly critical (6). The visitor is not entitled to pass judgment but he may legitimately ask whether the frame of reference which is most widely endorsed in many centres of training is broad enough to encourage the inter-disciplinary co-operation which is clearly needed for psychiatric progress. The dangers of a re-

stricted viewpoint have been illustrated in the past 3 years: the frosty reception given to the newly introduced "tranquillizing" drugs by psychiatrists with a bias against physical forms of treatment has been matched by the enthusiastic use made of the drugs by psychiatrists of a different persuasion(2). In many scientific fields work bearing on psychiatric problems has bombarded the clinical psychiatrist with data, theories and speculations, mined from the rich seams of the social and laboratory sciences, psychology, statistics and public health, to name only the more important. The contribution of the investigators in these fields constitutes the most hopeful and the most challenging feature on the American psychiatric scene: it demands continual assessment by clinical psychiatrists who are in danger of becoming passive, if receptive, junior partners in what should be a joint enterprise of collaboration. More is now demanded of the psychiatrist than a medical background, an administrative proficiency and a close acquaintance with one concept of individual psychopathology. "Research has become big business" according to the head of the Biological Sciences Division of the Office of Naval Research(22), and as very large sums of money become available, psychiatrists are being led or induced to assume a different role from that to which most of them have been accustomed.

Fortunately, there is no reason to believe that any single viewpoint can long dominate North American psychiatry. The 1956 centenary celebrations of Freud's birth demonstrated the high standing of psychoanalysis in the country but did not conceal the restless dissatisfaction which exists not only among the small number of avowed antagonists of the psychoanalytic movement(3) but also among its proponents. In Great Britain psychoanalysis has been in contact with, rather than a part of, academic psychiatry: its concepts have been transmitted through a semi-permeable membrane of critical examination and testing, and the rate of absorption has been slow. In the U.S.A. a remarkable attempt has been made in many centres to ingest the whole system, python-like, into the body of academic opinion. The post-prandial reaction seems now to be leading towards the elimination of indigestible matter and waste

products: in evidence are the pronouncements of leading psychiatrists like Whitehorn and Appel; the new stress being laid on the psychotherapeutic method as a research tool; the supplementary investigations of the psychotherapeutic process itself; and the experimental testing of many psychodynamic hypotheses, though for much of this work the credit must go to psychology rather than to psychiatry(13). It seems highly probable that what is of lasting value in psychodynamic theory and practice will find its way into both British and American psychiatry; the difference lies in the tempo, and in the route which is being taken.

There is, however, only a partial view of American psychiatry to be obtained from contact with the medical and allied professions. Since the early days of the mental hygiene movement psychiatry has entered into the fabric of American life in a way unparalleled elsewhere and which finds expression to-day in the widespread quest for "mental health." No one interested in mental illness can disregard "mental health" which, although it eludes all attempts at definition, remains a live and vigorous concept. To the visitor it seems that "mental health" would become a less nebulous objective if three separate uses of the phrase were always distinguished. "Mental health" is employed first as a euphemism for mental illness, and may as easily screen an inquiry into schizophrenia as into schools. Secondly, and more legitimately, it designates the campaign for the viewpoint of those workers who apply skills developed in the field of public health to psychiatric problems; workers for "mental health" in this sense concentrate on the group rather than the individual as the unit of study, conducting morbidity and other surveys and paying close attention to the principles of epidemiology and statistics. But in its third guise "mental health" can be understood only by identifying what one authoritative subcommittee has termed "... the flavour of morals and ethics, religious fervour, personal investment, unvalidated psychological concepts, value judgments, psychiatric theory, political science, welfare movements, and cultism(11)." It is more likely to be the task of the social historian than of the psychiatrist to analyse the full

range of "mental health" activities in America today. Meanwhile the sociologists have begun to clear the way (9, 10, 26). Psychiatrists should follow their progress closely if they wish to grasp the social implications of their own activities.

The signs augur a phase of self-examination and reassessment in American psychiatry. It is to be hoped that the forthcoming report of the Joint Commission on Mental Illness and Mental Health will indicate the direction which is to be taken. Whatever that may be, it is certain to influence those of us who work in other countries and who will hope to profit from the achievements and even the mistakes which will ensue. Meanwhile the achievements of British psychiatry in recent years testify to the progress which has been made and illustrate the shaping of many advances by social factors. No psychiatrist concerned with the welfare of his subject in either country can surely doubt that a closer professional and personal interchange will result in mutual benefit.

CORRECTION AND RETRIBUTION IN THE CRIMINAL LAW

LAWRENCE FRIEDMAN, M.D.¹

It is impossible not to sympathize with Dr. Richard Board's effort to establish a criterion of criminal responsibility devoid of moral judgement (*Am. J. Psychiat.*, 713: 332, Oct. 1956). The approval which the article will doubtless compel from enlightened readers witnesses the shift of concern from judgement to correction that so regularly follows increased understanding. Different human interests make different uses of old institutions, and criminal jurisprudence is showing an undeniable tendency to regard itself as a doctor of society. In this role it will be assisted by Dr. Board's clarification of therapeutic rationale. However, psychiatrists have found by painful experience that advice is effective only to the degree that the advisor both understands the problem presented to him, and the perplexity from which it arises. It would seem that Dr. Board, in reflecting the new interest in correction, has permitted a certain relaxation of these requirements, and has overlooked considerations appropriate to his role both as psychiatrist and operational philosopher.

I

As a philosopher Dr. Board proposes that moral responsibility be discarded as a concern of the law because "moral responsibility [is] an idea having a metaphysical content dealing with free choice between the values of good and evil," whereas "the law constitutes an operation exclusively confined to the natural world of cause and effect." Though briefly stated and undefended, the first assertion is as controversial and unsettled as an assertion may be. It is familiar as the argument used by a group of critics to impeach the ethics of modern psychiatry. Psychiatrists, as good citizens, are wont to protest that the causal link between a person's actions and his total personality, far from excusing his behavior, is the prime requisite for attaching moral responsibility, which could not sensibly be attached to a freakish, spontaneous act totally unrelated to the personal-

ity (3). It is this fact to which Freud refers when he says "Obviously one must hold oneself responsible for the evil impulses in one's dreams. In what other way can one deal with them? Unless the content of the dream . . . is inspired by alien spirits, it is part of my own being" (1).

But if it is an error to regard moral responsibility as opposed to cause and effect, it is no less so to regard the law as "an operation exclusively confined to the natural world of cause and effect." For the law is not principally concerned with establishing what is and has been, nor in predicting what will be, but rather with the use of these in deciding what *should* be. Following the example of the law, Dr. Board himself steps outside the natural world of cause and effect and there finds that what is "worthy" of society is correction rather than condemnation and punishment.

This is a suggestion for which we should thank him if he recognized it as a suggestion. As the "operational meaning or 'cash value' of the concept (of criminal responsibility)" we are more likely to find ourselves somewhat suspiciously counting our change. For example, Dr. Board's operational analysis of criminal procedure reveals to him the workings of protective, corrective and humane principles, and something else which he calls "vengeance to the criminal." Although this last is apparently to be found in the operation of the law, it is not therefore, as you might expect, a part of its operational meaning. It is a "contaminant." This strange qualification of an operational concept (in which the metaphysician will recognize the old "accidental attribute") is required because the investigator finds such aims "rejected as unworthy of society,"—rejected, evidently by Dr. Board, since they are retained as contaminants by society. Such an operational analysis, which includes the import of some operations and excludes the significance of others, resembles not so much operational philosophy as it does operative surgery. Post-operatively a contaminant is

¹ V.A. Hospital, West Haven, Conn.

all that remains to the criminal law of the concept of justice which afforded it such satisfaction in better days. If we agree to this we must be convinced that talk of retribution and debts to society is a rare and uncharacteristic way of referring to criminal responsibility.

Radical surgery, of course, has its indications and Dr. Board is obviously more interested in finding a workable meaning of criminal responsibility than elucidating the common meaning. Accordingly he states that "while these [his own] value judgments may have metaphysical origins, carrying them out requires scientific rather than metaphysical conceptions." If there is no way of applying common concepts, they must be excised. But is there not a sense in which the law can be considered an operational definition of moral responsibility? The problem of workability only arises with recent attempts to make exceptions to what has in criminal law been an obviously retributive system (and which remained so long after it recognized insanity). It is a discomfiting thought that the problem of how to be more discriminating in applying the concept of moral responsibility is here solved by eliminating the entire concept. One can almost sympathize with those who learn from this not to discriminate.

We have here one further example of the failure (well illustrated in modern philosophy) to distinguish between explication and legislation. Explication is the replacement of a vague and shadowy notion with a clearly defined concept that comes as close to it as a clear concept can come to a vague one. If that vague notion is sufficiently obscure and its import distasteful to the explicator, he will be overwhelmingly tempted, while concealed in the dark, tortuous alleys of confused meaning, to secretly assassinate the offending concept and sponsor forth some favorite imposter in its stead. Legislation is so much simpler than explication and can look so like it. But perhaps of all philosophers, it is the operationalist who should have the greatest patience with the vaguenesses of the law, for this at least is already a set of operational definitions and having anticipated, so to speak, the greatest part of the

analysis, may be permitted its gaucheries and inconsistencies; if it had none the operational philosopher would have no job. Part of this job is to determine by the uses of the law, why certain wrongs are exempt from the need for retribution. To say that all are exempt, as Dr. Board does, is to abandon explication for legislation.

II

But if, as philosopher, Dr. Board should have seen how intrinsic the notion of retribution is to the criminal law, as a psychiatrist he would be expected to recognize how retributive is the punishment demanded by the conscience of the people whose law, after all, it is.

When Dr. Board asks "Where in the range of psychodynamics does moral responsibility suddenly or gradually appear?," his rhetorical question exposes itself to an answer. To be sure, and this is his main contention, nowhere do condemnation or moral directives appear as statements of psychology, but they do certainly appear *in* statements of psychology, and it is in psychology that these moral directives first receive their meaning(2). This being so, the psychiatrist is in the very best position to appreciate those retributive, punitive requirements of the mentality that creates the law. To nevertheless ignore them in the created law is as much a disservice and as ultimately futile as to pretend that people's consciences can serve solely as a guide to better behavior and never as a source of remorse or indignation.

But not only will the wise psychiatrist thus confirm what the careful philosopher finds in his analysis of criminal law; he will have the additional advantage of anticipating the confusion and contradiction seen in its application. He daily points out the ambivalence and complexity of what his patients consider to be fairly simple attitudes. He should not be the last to recognize that an institution like the law is used to implement many social aims, any two of which would be entirely consistent and compatible only by the most extraordinary accident. As a psychiatrist it better suits him to instruct the public in these divergences than to conceal them behind a false rationalization. The apparatus

the law is used for marriage counseling, child-rearing, psychiatric steering, social change. It is also used to avenge injustice. Depending on the temper of the times some of these aims may eclipse others. Eclipsed aims however vanish no more readily than repressed ideas, and will not be exorcised by labeling them contaminants. To say that punishment as a method of rehabilitation is given in the same educative spirit as in punishing a child" is to say that punishment is only rarely a method of rehabilitation. Witness the remarks of the magistrates who dispense the greatest quantity of justice in our culture.

The lesson to be learned from Dr. Board's interesting attempt to rationalize the law by heeding only its protective and corrective aims is that the search for the compound of conflicting interests served by the law cannot be impatiently replaced by a simpler reconstruction. Such a reconstruction is irrelevant to the need the law fills, which is to bring society's complicated aims to just that kind of expression demanded by their relative weights. Opinions based on an autistic law created by the expert will be properly held, in the apt words of Dr. Board's quoted opponent, not "responsive to the question the jury must answer."

The only fruitful method is to continue the difficult and frustrating attempt to follow out all the hints that the exercise of the law provides. If there is a difference between society's attitude to the child, where punishment is educative, and its attitude to the adult criminal, this is operational evidence that culpability in the law has some relation to psychological development, and it provides operational hints as to what qualifies moral guilt in the mentally ill criminal. Does an ego require a certain integration before guilt seems appropriately applied to it? In punishing are we interested in counterbalancing an action reflecting a wrong sense of values, and do we therefore require a minimum of apprehension of facts or reality-testing in order to insure that the distortion is really one of values? Are we perhaps offended by only

certain kinds of wrong value pictures? Whatever the answers, we will not discard them for inconsistency, since we know beforehand that under certain circumstances we will exercise sympathy where we might indignation, and that people will sometimes be more concerned about therapy than justice.

SUMMARY AND CONCLUSIONS

Dr. Board's objectives can only tend toward a happier society. His failure to distinguish between suggestion and analysis prejudices his worthwhile objectives in the following ways:

1. It leaves him unarmed against the resistances of society which go unrecognized.
2. It compromises the effect of the psychiatrist's most potent weapons,—expert advice and education, by concealing them in a tendentious special plea for the values of the psychiatrist.
3. In the manner of so many current political positions, it blurs the meaning of society's conflicting values by insisting that they are perfectly realized in the tissue of compromises and violations that alone can give them expression.
4. Finally, one suspects that there will come a time when the psychiatrist, accustomed to the stationary ethical foundation he has artfully built and unprepared for the heaving sea of felt principles, will feel in himself the upsurge of the rejected "contaminant" and be overcome by a moral malaise without remedy.

REPLY TO DR. FRIEDMAN

RICHARD G. BOARD, M.D.

In my article, "An Operational Conception of Criminal Responsibility," I tried to be as specific and precise as I could so that any inconsistencies in logical development would be easy to spot. Dr. Friedman believes that he discerns such mistakes. I hope that my objections to his objections will reassure him that I am not unfamiliar with the issues he has raised.

To begin with, Dr. Friedman points out that I did not document my assertion that the concept of moral responsibility was a metaphysical rather than scientific idea. I didn't think it was necessary to prove it for several reasons. First, what moral responsibility is, or is not, was not a central issue in my article which was concerned with setting forth an alternative to that vague idea. Second, while the subject may still be disputed by system philosophers, I believe that it is no longer taken seriously in science. For example, in one of the very articles cited by Dr. Friedman, Dr. Robert Knight makes it abundantly clear that any concept involving free choice has no place in scientific theory.

Dr. Friedman's next objections result from his failure to differentiate between criminal law as a system of proscriptions about behavior and the procedure of applying this system in the courtroom. For he quotes me as saying "the law constitutes an operation exclusively confined to the natural world of cause and effect" whereas the statement was: "the administration of the law constitutes etc." However Moses got his commandments, he had to descend the mountain to administer them in the valleys of cause and effect. Replacing a metaphysical ritual in administering criminal law by a deterministic, scientific procedure does not involve throwing away the value judgments such as justice blueprinted in the laws to be administered.

In the midst of this confusion, Dr. Friedman introduces a quotation from Freud in order to show that moral responsibility has something to do with cause and effect. Please note that Freud uses the term *responsible* rather than *morally responsible*. What does *responsible* mean in this context? To clarify

this, let me translate the quotation into more precise language: "Obviously, a constellation of forces within the individual results in the 'evil' impulses in his dreams. What other forces can cause them? Unless the content of the dream . . . is inspired by alien spirits, the location of these forces causing the dream is within the dreaming individual." Perhaps also implied is this: "And so it is to this individual and these forces that we apply the forces of therapy." Now certainly this statement is naturalistic enough. With but slight modifications it could apply to almost any animate or inanimate event. In this sense, a landslide is responsible for obstructing traffic and a murderer is responsible for his victim's death. "Responsibility" is used as a way of referring to cause and effect linkage and to locate the forces involved within a certain individual. And it means no more. But this is not the moral responsibility of the courtroom nor the criminal responsibility founded on that concept. If it were, how could we find even the sickest dreamer "irresponsible." If this kind of courtroom responsibility indicates causal linkage between actions and the personality, who could ever be judged irresponsible? What causes the "freakish, spontaneous act totally unrelated to the personality"—an alien spirit? As scientists we would do well to drop the whole idea of responsibility. It isn't needed to get things done with everything in the universe except human behavior and it isn't needed to get things done with human behavior. In my article the quantitative operational concepts of deterrent efficiency and efficient punishability replace the confusing idea of criminal responsibility.

Dr. Friedman's concern that I may have introduced some value judgments of my own in pronouncing retributions or vengeance an unworthy contaminant in the judicial process seems to stem primarily from his failure to appreciate that there are 3 general levels involved in criminal law. First, there is the blueprint for behavior, the laws themselves. Second, there is the blueprint of how to administer the laws. Third, there is the administration of the law by the all too human

judge and jury. My paper concerned the second level, the blueprint of how to administer the law, explicating the current value systems involved and the logic of their application to the natural world of criminal behavior. Regarding the value judgments inherent in the blueprint for administration, my point was that they have gravitated away from retribution and toward correction. Such things as public hangings, floggings, cruelty toward the imprisoned and other food for vengeance are discouraged these days because of this change in values regarding the administration of the law. Retribution and vengeance toward the criminal still flourish, as Dr. Friedman points out, but only at the third level, the all too human performance in the courtroom. But they are continually hedged in and circumscribed by the blueprint of administration. I say all too human because the law and the blueprint for its administration seek to be better than any man—more impartial, less vengeful, etc. This is one reason we prefer a government of law rather than men and regulate the administration of law rather than trusting too much to the emotional vagaries of judge and jury. In regard to the trend in values characteristic of the blueprint for administering the law, the emotions of judge and jury, vengeful or otherwise, stand as contaminants in the judicial process of government by law. In view of the progress already achieved in circumscribing these contaminants, Dr. Friedman need not be too pessimistic about further improvements.

Next comes Dr. Friedman's assertion that I was too selective in my operational analysis of criminal procedure in conspicuously omitting vengeance toward the criminal. I have already indicated why this portion turns out to be a contaminant in regard to enlightened administrative blueprints. But Dr. Friedman's conception of operational analysis intrigues me. Unfortunately, there has been a trend toward broadening the concept of operational analysis since Bridgman first formulated it until it can cover almost anything. Thus it is becoming a favorite of philosophers. It is possible that Dr. Fried-

man, in his role of careful philosopher, has achieved the *reductio ad absurdum* for this trend. As I get it, he seems to feel that any vague idea can be operationally analysed—even the magical rituals of the primitive, I would suppose. But there are concepts that are operationally meaningless and in such cases there is no alternative but to legislate rather than explicate. I regard moral responsibility as just such a concept. The fact that an elaborate courtroom ritual exists whereby it is supposedly applied confers no more operational validity upon it than conceiving of golden mountains will make one rich. As I indicated explicitly in my article, I set out to redefine criminal responsibility and made no bones about the fact that I was not intending an operational analysis of moral responsibility. I don't think any is possible. Dr. Friedman need not fear that the concept of moral responsibility will be assassinated in "the dark, tortuous alleys of confused meaning." That is where it thrives.

Regarding correction *vs.* retribution as an aim of the law itself, I am reminded of Professor Stace's observations on the subject. The impositionist theory, personified by Moses obtaining the law from God, holds that laws are imposed on mankind from without. The immanent theory holds that laws are evolved by mankind. Science has tended to confirm the latter. The law is viewed as an institution evolved by societies to maintain themselves. As adaptive mechanisms the laws and even the idea of retribution are corrective mechanisms maintaining society. Like many corrective mechanisms, retributive law is as inefficient in the long run as a neurotic symptom.

Having been jumped so frequently between the roles of philosopher and psychiatrist in Dr. Friedman's paper, I would seek final asylum in his role of wise psychiatrist. He had some nice things to say about my article before the inevitable, "however," and this suggests to me that our agreement may be more extensive than our differences. In turn, I have had to be abrupt and unconstructive. I hope that both of our discussions will stimulate further study of my article.

SOME PSYCHIATRIC NOTES ON THE *ANDREA DORIA* DISASTER

PAUL FRIEDMAN, M.D.,¹ AND LOUIS LINN, M.D.²

On July 25, 1956, at 11:05 p.m., the Swedish liner *Stockholm* smashed into the starboard side of the Italian liner *Andrea Doria* a few miles off Nantucket Island, causing one of the worst disasters in maritime history. The authors were passengers on the Europe-bound *Ile de France* and spent approximately twelve hours, independently, interviewing and observing the survivors, the crew of the *Ile de France* who participated in the rescue operation, and the passengers aboard the *Ile de France*. It must be noted that the cause of the disaster was purely a matter of speculation at the time and there was no factual basis for establishing culpability for it. Subsequent inquiries succeeded in establishing the circumstances of the accident, and the authors are gratified that their observations can now be measured in terms of confirmed facts and thus assume more realistic value. For, as psychiatrists and psychoanalysts who happened to be on the spot, we were in a unique position to make immediate observations. Our data, carefully recorded after interviews with a large number of people, do not constitute a systematically scientific study of the experience, but may represent a modest contribution to the psychology of disasters.

THE STATE OF INITIAL PSYCHIC SHOCK

The emotional state of the survivors may be divided into two distinct phases: the state of initial psychic shock and the recovery phase. During the phase of initial shock the survivors acted as if they had been sedated. It is noteworthy that but a minimal quantity of sedative medication had to be administered during this time. Thus, it was as though nature provided a sedation mechanism which went into operation automatically in most cases. The survivors presented themselves for the most part as an amorphous

mass of people tending to act passively and compliantly. They displayed psychomotor retardation, flattening of affect, somnolence and, in some instances, amnesia for data of personal identification. They were nonchalant and easily suggestible.

Comment.—The attitude of helpless dependency identifies this condition as a state of emotional regression in which people who are normally capable of functioning on an emotionally mature, adult level become childlike in their feelings of personal inadequacy and in their tendency to overestimate the powers of those offering help and leadership. In their state of shock, the survivors of the *Andrea Doria* could be compared to the survivors of the concentration camps who were found to have developed a state of affective anesthesia as a defense against the dangers and anxieties to which they were continuously exposed (7, 8). As early as 1918, the same reaction pattern was observed by Jones (9) as well as by Ferenczi, Abraham and Simmel (2) in victims of war shock; and when Freud (5) spoke of a "protective barrier against stimuli" (*Reizschutz*) he actually defined a mechanism which is probably mediated by the ascending, activating reticular system which protects the central nervous system when exposed to stimuli of excessive intensity. Because of this protective mechanism the survivors of the *Andrea Doria*, at first, could not be approached or induced to talk.

THE PHASE OF RECOVERY

After their initial shock had worn off, it became possible to question the survivors. As a matter of fact it was usually unnecessary to ask questions, since so many of them had a great need to tell their story. And they did tell their story, over and over again, to anyone who would lend a willing ear. Characteristically they showed pressure of speech and an apparently compulsive need to tell the story again and again, with identical detail and emphasis.

¹ Associate Attending in Neuropsychiatry, Beth Israel Hospital, New York City.

² Associate Attending Psychiatrist, Mount Sinai Hospital, New York City.

Comment.—We were impressed with the similarity between these repetitive narratives and the repetitive dreams of the traumatic neurosis. Each represents a psychological reliving of the trauma, as part of an attempt to master an experience that had proved overwhelming.

PREJUDICES AND PARANOID ATTITUDES

We were struck by the frequency with which the survivors who spoke to us were angered. They expressed certainty that the accident was the fault of the *Andrea Doria*, even though the details of the catastrophe—such as the extent of the survivors' misery, the irreparable loss of the beautiful ship, the relatively intact state of the *Stockholm*—favored sympathy on behalf of the *Andrea Doria*. This prejudice was based on the *a priori* acceptance that Swedes are dependable, faultless sailors and people of impeccable integrity and reliability, while Italians on the other hand are childlike and irresponsible, tending to pursue their pleasures instead of their duties.

Comment.—It is interesting to remember at this point that during hearings investigating the causes of the *Titanic* disaster in 1912, the term "Italian" was freely used as a synonym for "coward." "There were various men passengers," declared Steward Crowe of the *Titanic* at the U.S. inquiry, "probably Italians, or some other foreign nationality other than English or American, who attempted to rush the boats." This contention, proven false, formed the basis for a successful libel suit against this officer. It is also somewhat ironic to recall that in his book on the *Titanic* disaster, *A Night to Remember*, published less than a year before the *Andrea Doria* catastrophe, Walter Lord (11) expressed the view that some of the prejudices of the age went down with the *Titanic*, notably the belief in the superiority of Anglo-Saxon courage. Such a notion was proved overoptimistic by opinions voiced aboard the *Ile de France*. The absolute necessity for finding a scapegoat, for locating somebody who was at fault, found at outlet once again in the paranoid projection of prejudice on the part of people on the *Ile de France*; not only demonstrating that stereotype thinking

is still prevalent, but dramatizing its capacity to dominate opinion during periods of crisis and its influence in distorting perception and judgment.

Such attitudes are familiar expressions of the quest for a scapegoat, a psychological device for turning aggression outward. It is part of the overall attempt to master an overwhelming trauma. The survivors' tendency to blame the *Andrea Doria* for their misery derived from their feeling of having been failed. They suffered a narcissistic injury which may be compared to the feelings of a child who finds that the strength of his father has turned out to be a fallacy. Let us not forget that the *Andrea Doria* had been considered unsinkable, which conveyed a great sense of security in her passengers; yet there they were having to abandon her and being abandoned by her, experiencing the inability of a parent to cope with disaster.

The facts are that the crew of the *Andrea Doria*, with the expected exceptions, acted with generosity and even heroism. It has been recorded by Cornelius Ryan (13) in an article for *Collier's* and by Walter Lord (12) in an article for *Life* how an Italian cabin-class waiter and several Italian crew members cooperated in trying to free the wife of a passenger from beneath a collapsed partition, spending five hours in the futile effort. Many other instances of helpfulness and altruism on the part of crew members are on record, leaving no basis for condemnation.

Expressions of prejudice were not confined to fixing the blame for the accident on the *Andrea Doria*, but also manifested themselves in the contempt voiced by some passengers on the *Ile de France* toward Italian immigrant survivors because of their uncontrolled demonstrations of despair. To some who expressed these feelings it was explained that patterns of emotional expression are culturally determined and that they vary, in a given national group, from one economic stratum to another. It was also indicated to them that the control of emotional expression under stress is not a reliable measure of courage and strength of character; furthermore, that from a psychiatric point of view the expression of one's true feelings, particularly during bereavement,

serves a useful adaptive function in the mental health of the individual.

Such opinions among *Ile de France* passengers thus were clearly based on paranoid projections of stereotyped prejudice, in contrast to the reactions of the rescued whose resentment toward the *Andrea Doria* stemmed from the violent destruction of their sense of security and dependence.

THE PROBLEM OF COMMUNICATIONS

The most frequently voiced charges were: that no announcement had been made about the nature and gravity of the accident, and that no concerted rescue effort was made.

Comment.—These have been answered by the fact that the first impact of the collision caused a power failure on the *Andrea Doria*, putting the public address system out of commission. Moreover, the ship rapidly developed a severe list which, coupled with oil slicks on the decks, made it imperative for each person to save himself from sliding into the sea. These circumstances also made it almost impossible to circulate information on foot. As a matter of fact, Italian crew members did make their way about on the sharply inclined decks, urging passengers to remain calm, and there was indeed very little panic.

LEADERSHIP

The foregoing facts compel a consideration of the problem of leadership in crises. Because of the conditions on the *Andrea Doria* just described, groups of people were largely immobilized and isolated; this created a necessity for each group to evolve its own leader. In several instances, priests and nuns stepped into the breach. By virtue of their training they were prepared to do so, just as the predominantly Italian Catholic immigrant group was prepared by training to accept their leadership. Primarily they participated in the practical problems of the rescue operation, only secondarily providing religious solace to those who asked for it. In other groups there were individuals not otherwise identifiable who likewise assumed leadership voluntarily.

Comment.—The willingness of some people to assume leadership of a group in dis-

aster situations has repeatedly been observed, and a systematic study of such individuals might help us to identify the qualities that make for leadership, enabling us to concentrate our civil disaster training on such persons. The existence of a corps of trained people endowed with qualities of leadership may make the difference between success and disaster in community emergencies. A leader who understands the psychological importance of identifying with a group, as a device for combatting feelings of individual helplessness and despair, will make use of techniques which promote positive group action. Not only is effective leadership the most important weapon in combatting mass hysteria, but, as stated by Sperling (14), mass hysteria as such can be defined as a failure of leadership. Whether a group reacts to a crisis with self-control and cooperation or with egotism and chaos depends almost entirely upon the quality of leadership, and the vital importance of developing able leaders is well illuminated by Freud's (6) statement in the *New Introductory Lectures on Psychoanalysis*: "A psychological group is a collection of individuals who have introduced the same person into their super-ego, and on the basis of common factor have identified themselves with one another in their ego."

CHILDREN IN DISASTERS

The application of the "women and children first" principle on the *Andrea Doria* resulted in some poignant and, in at least one case, tragic separations and isolations. It can be said that this principle, which prevails in our culture during catastrophes, frequently results in the isolation of children from their parents with possibly disastrous psychological consequences.

Comment.—This view finds ample support in the Freud-Burlingham (4) reports on *War and Children*. During the bombings of London in World War II it was repeatedly observed that children exposed to extremely violent bombing scenes, even those partly buried by debris, showed no particular signs of having been affected if they were in the care of a parent during such incidents. Bombed-out children would arrive at a shelter, in the middle of the night, showing no

undue disturbance when accompanied by parents or by familiar parent substitutes. Serious psychological disturbances were confined largely to children separated from their parents during such experiences. It was the main conclusion of the Freud-Burlingham reports that such disasters as war have comparatively little significance for children so long as they only threaten their lives or material comforts, but become enormously important the moment they break up family life and uproot the first emotional attachments of the child within the family group.

In another study of emotional reaction of children to disaster, Bloch, Silber and Perry (1) clearly established a post-disaster increase in dependency needs characterized by symptoms of regressive behavior. They observed that a greater need for belonging and a reaching out for others were typical disaster responses in children, but that such manifestations would tend to be arrested or at least alleviated by the presence of a parent during disaster situations.

These principles found a practical application during the Arab-Israeli war of 1948 when the Israelis adopted the practice of requiring one parent to remain with the children if the other were assigned to a hazardous mission, so as to minimize the likelihood of children becoming doubly orphaned. The authors are convinced that a modification of the "women and children first" rule by insistence that a parent accompany the child, even if the only parent available be the father, would represent a sound application of modern psychiatric insights.

OFFICIAL IDENTIFICATION LISTS

The lack of an official list of survivors contributed to the delay in the reunion of families separated during the disaster. As far as we could ascertain, such a list was not initiated with the rescued during their stay aboard the *Ile de France*; this and similar delays on other vessels and at collection centers may account for the fact that several days passed, in some instances, before families were reunited.

Comment.—Prompt establishment and publication of such identification lists is an important leadership device in combatting

panic and maintaining morale. This device serves a twofold purpose. First, it is reassuring to the bewildered survivor to be recognized as an individual; the mere recording of his name, address and next of kin helps to re-establish, in his mind, the intactness of his shattered ego. The instances of amnesia during the initial psychic shock phase, to which we referred above, tend to support this concept. Secondly, to expedite the reconstitution of broken family units is a matter of equal psychiatric importance for the isolated individual. A considerable number of passengers on the *Andrea Doria* were immigrants coming to the United States, for whom the catastrophe represented a complete loss of identity in both the physical and the psychological sense. For members of this group, the loss of their passports constituted the end of their individuality; in contrast to the tourists, for whom the loss of passports was merely a transitory predicament which failed to damage their identity: they could always return to their background, their money and their roots. But for the immigrant the passport symbolized not only his individual identity, but also his sense of belonging, and it is not surprising that to save it was of greater importance to him than the saving of physical property. Those who could save their passports managed to maintain their pride, even if they had lost all their material belongings; those who failed to save them became "stateless persons," temporarily at any rate, whose whole sense of belonging went down with the *Andrea Doria*. The publication of an identification list of survivors would have brought a great measure of relief to these people for whom the loss of a passport also meant a discontinuation of their body image, a psychic loss which would have been relieved by being included on such a list.

REACTIONS AMONG THE ILE DE FRANCE PASSENGERS

Many lay persons, in subsequent discussions of the *Andrea Doria* disaster, have remarked: "How depressing it must have been! It must have cast a pall over the rest of your trip." This attitude, which implies a deep identification with the victims, can be

summarily dismissed. To our knowledge, there were only a few passengers who became so depressed that they decided to interrupt their trip to Europe and return home when the *Ile de France* docked at New York. It was not difficult to ascertain that these people had been depressed prior to their departure and that their depression was merely reactivated by the events at sea. In general the impact of the catastrophe did not have as disruptive an influence as one might think.

Comment.—It must be remembered that most of the passengers on the *Ile de France* were asleep at the time of the collision. They were stupefied when, upon awakening, they found out what had taken place, and manifested rather a feeling of shame and of having been cheated of the experience. One of the authors vividly recalls his feelings of anger at not having been awakened and of deep disappointment when his services were not needed. The passengers somehow reminded one of soldiers during a war who have remained behind the front lines and never got to see a real battle. This usually generates a sense of guilt, which no doubt was also present in all the passengers who showed a readiness to help as much as they could and even displayed acts of generosity.

All this points to a confirmation of the principle that guilt can be a positive force of social good when given proper channels of expression in terms of morality and social approval; in the process, personal neurotic anxiety and depression may be relieved.

PERCEPTUAL DISTORTION

Several passengers on the *Ile de France* were awakened by the sound of lifeboats being lowered to pick up the *Andrea Doria* survivors and went back to sleep with the thought, "this is only a drill and is of no concern to me." One man expressed this aloud to his wife and got up, reluctantly, only at her insistence that drills do not take place at 2 a.m. A particularly fascinating experience was reported by a man who heard voices outside his cabin. He got up and saw several lifeboats in the water. The people in them wore the conspicuous orange-red life preservers, and in the brilliant spotlights of the ship these colored life preservers had, to

his mind, a festive quality. The sounds outside, which were actually expressions of misery, sounded to him like laughter and gaiety. It seemed, to quote him, "like a carnival in Venice." He went back to bed muttering to himself that this was carrying the Frenchman's love of fun a little too far and that one should not cavort so noisily in the middle of the night. He was just falling asleep when the true significance of what he had seen hit him, and he leaped from his bed and got dressed. Several others reported hearing sounds outside the portholes which they interpreted as sounds of festivities and merriment.

Comment.—In each of these cases we find perceptual distortions which parallel those taking place in sleep. Stimuli received during sleep are transformed into dreams that encourage the continuance of sleep. In our examples the subjects were already awake, but interpreted their sensory impressions in such a way as to justify a return to sleep; i.e., in a way designed to relieve anxiety which would disturb sleep. Instances of sensory distortions under similar disaster circumstances are described in Lord's (11) book on the *Titanic*:

Individual voices were lost in a steady, overwhelming clamor. To Fireman George Kemish, tugging at his oar in Boat 9, it sounded like a hundred thousand fans at a British football cup final. To Jack Thayer, lying on the keel of Boat B, it seemed like the high-pitched hum of locusts on a midsummer night in the woods back home in Pennsylvania.

PROPERTY

During the evacuation of the *Andrea Doria*, most passengers were forced to abandon their belongings. Such exigencies throw an illuminating light upon feelings toward property in disasters. What do people try to save under these circumstances? What do they choose to take with them in the process of trying to save their lives?

The main concern of the immigrant group was focused on the effort to save their passports, disregarding articles of material value. For members of this group, as we have noted, a saved passport meant the continuation of body image, the tangible affirmation of survival, the maintenance of their sense of belonging and pride. But of course, too,

the saving of valuables appeared to be secondary. In some instances, women already enjoying the safety of a lifeboat would drop their jewelry into the ocean.

Comment.—One might speculate about the sacrificial symbolism of such acts which imply the offering of sacrifice as an expression of gratitude for the sparing of life. The fact that a lady who had saved her mink stole became the object of ridicule would seem clearly related to such feelings. While behavior observed during the sinking of the *Titanic*, like our notes on the *Andrea Doria* catastrophe, revealed a rich variety of attitudes toward property, the former would equally tend to confirm the existence of a need to offer material sacrifice in exchange for life. The following examples are taken from records of the *Titanic* affair. One person took with her a musical toy pig, another a bible, another a revolver and a compass, another only books, another four oranges. Two outstanding instances were noted in Lord's book, both expressing a curious disregard for valuable belongings: one was the case of Mrs. Dickinson Bishop who, having left behind 11,000 dollars' worth of jewelry, sent her husband back to the cabin for her muff, the other, the famous decision of Major Arthur Peuchen to abandon 300,000 dollars in stocks and bonds and to take merely a good-luck pin and three oranges. Although there were others, like Mrs. Adolf Dyker, whose main concern was the saving of their jewelry, the outstanding feature of property rescue was the secondary importance attached to articles of monetary value. The authors found a striking parallel, in these reports, to incidents observed in the more recent disaster.

CLOTHING

In the course of leaving the *Andrea Doria*, most passengers had to shed their shoes and partially also their clothes. Thus they came aboard the *Ile de France* shoeless and, many of them, scantily clad. Crew and passengers of the rescue ship were generous in their contribution of clothing articles; yet it caught our attention that some of the survivors, mainly among the younger people, were not too eager to accept the garments

thus offered to them. But their attitude was in sharp contrast with that of the majority who felt deeply ashamed at being unclad and, when given clothes, expressed their feelings of becoming dignified human beings again.

Comment.—These people looked upon clothing—as Flügel(3) observed in his brilliant exploration into the psychology of clothes—as protection against the unfriendliness, the enmity of the world as a whole, and as reassurance against the absence of love and security. Being in unfriendly surroundings—and to these people, who had to abandon the familiarity of their own ship, the chilly decks of the *Ile de France* must have appeared unfriendly—their natural tendency was to button up, to wrap garments around their bodies. They felt agreeably strengthened and supported by clothes in such circumstances.

It was interesting, therefore, to speculate on the motivations of those younger people who hesitated to accept the offers of clothing. One might ascribe to them, on the one hand, a feeling of bravado and assumed poses of heroism, possibly tending to exploit their situation in the hope of obtaining greater, more substantial rewards upon their arrival in New York, in the manner of a child who rejects a small toy while waiting for a bigger one. On the other hand, and perhaps more significantly, one might conjecture that they were also gratifying exhibitionistic fantasies; i.e., that they derived a narcissistic pleasure from the display of their bodies and that their lack of eagerness to accept clothes indicated a hesitation to sublimate it.

The behavior of both groups with regard to clothes, as well as the contrast between the two attitudes, provides a striking dramatization of Flügel's findings that articles of clothing are essentially in the nature of a compromise between conflicting elements for the establishment of harmony, in the same way as neurotic symptoms represent a compromise between conflicting and largely unconscious impulses.

SUMMARY AND CONCLUSIONS

We have presented observations concerning the phases of initial psychic shock and of recovery; prejudices and paranoid attitudes;

the problems of communications, of leadership and of children in disasters; the role of official identification lists; reactions among the *Ile de France* passengers; instances of perceptual distortion experienced by the latter; and various attitudes of the survivors toward personal property and toward clothing.

It is our hope that these observations will be of interest and possible value to those concerned with the psychological problems of civil disasters. The sinking of the *Titanic* in 1912 prompted major reforms and improvements in the physical aspects of safe navigation. Our psychological exploration of the *Andrea Doria* disaster, unsystematic though it be, points to avenues of further study into the following areas:

(a) Our notes on the role of prejudice in the development and resolution of crisis might merit the attention of the World Federation for Mental Health in its program for the prevention of social and individual emotional disorder through the systematic search for tension-reducing techniques. Our observations also emphasize the importance of paranoid reactions which are apt to arise in crises and to intensify conditions of chaos.

(b) The *Andrea Doria* experience points up the fallacy that all disaster training must be based on the expectation of nuclear warfare. Men of leadership caliber who shy away from preparations for atomic attack might participate more wholeheartedly in programs which emphasize training for such peacetime disasters as may befall anyone.

(c) The introduction of leadership devices that are based on established psychological needs. In our discussion of the "women and children first" principle we pointed out the desirability of having at least one parent accompany the child. The need for such practice has been amply demonstrated during previous crises in recent his-

tory. The importance of a speedy method of collecting and publishing survivor identification lists in disasters has also been established as a major device designed to aid survivors in maintaining their identity and to alleviate the traumatic content of their experiences.

The authors do not attempt to draw any general conclusions on human nature from the *Andrea Doria catastrophe*. But they do believe that the introduction of modern psychiatric principles in these areas will effect progress in important aspects of human welfare.

GROUP PSYCHOTHERAPY: INDIVIDUAL AND CULTURAL DYNAMICS IN A GROUP PROCESS

MARVIN K. OPLER, Ph. D.¹

Group psychotherapy depends on the dynamics of three processes. These processes are interwoven. Simultaneously, they involve the group, the individual and his cultural background. To date, there has been relatively little attention paid to this interweaving of three basic elements, their relative weight or effects, and the influence of one upon another during treatment. Since group techniques are used constantly and increasingly in hospitals and in private practice, a systematic approach to the total process is required.

This account discusses relevant aspects of the total process in which each term, the group, the initiator of therapy (the psychiatrist), treated individuals, and a variety of cultural backgrounds all play a role. For purposes of analysis, these relevant aspects of the listing just given must be determined. We therefore discuss them in the order of (a) the group, (b) the individuals and (c) cultural backgrounds represented by the physician and the treated individuals. In so doing, we shall deal with affective constants and variables associated with the terms listed as if they represented a continuum ranging from more optimal emotional conditions to those involving greater disturbance. We therefore begin with the group.

While most group psychotherapy involves Freudian presuppositions, Freudian notions of a necessary procedure are often lost in the complexity of the group process. We shall regard Freud's voluminous writings on psychotherapeutic procedures as being in "the public domain" and shall purposely avoid a list of specific references. However, such various works as Freud's *Interpretation of Dreams* or his *Constructions in Analysis* readily come to mind as instances of the assertion that therapeutic interpretations are really reconstructions of the past. In *Constructions in Analysis*, for example,

it is stated clearly that only further steps in the analytic procedure enable the therapist to decide upon "correctness or uselessness" of such constructions. This operational procedure in psychoanalysis, which Freud stated was conjectural, awaiting "examination, confirmation, or rejection" really accords well with the operational and exploratory character of most group sessions. However, Freud paid little attention to concomitant group influences in treatment sessions. Even in the *Psychopathology of Everyday Life*, the impression one has is that two-person situations, rarely with a modest audience of onlookers, predominated. Many of these instances involved the individual and his errors of omission or commission, acting alone.

What, then, does the group—even a somewhat amorphous and experimental one—add to this picture? The last decade has seen great development of research interest in the organization and functioning of small groups. Hare, Borgatta and Bales have assembled much of this literature(5). From mountains of research, the flowers of information are rare, but they have definite uses, when catalogued, for group psychotherapy. In 1940, the anthropologist, Chapple, discovered all persons have characteristic or normative rates of communication, described as interaction levels. Experimentally, the rates showed modification by interaction constants of others in the same situation. For example, as politeness or shyness in strangers wore off as a function of time spent together, each approached their already noted, or normative, levels(3).

Psychiatrists add to this a crucial observation, namely that a mental illness may drastically modify such normative interaction levels of personal communication still further. Again to cite theoretical statements of this idea, already in the public domain, one could note that this particular observation formed a large part of Sullivan's *Interpersonal Theory of Psychiatry* or of Fromm-Reichman's *Principles of Intensive Psy-*

¹ Vis. professor of anthropology (social psychiatry), department of psychiatry, Cornell University Medical College, New York City.

chotherapy. Stanton and Schwartz's *The Mental Hospital* is a third well-known work replete with such instances. What is arresting about these three well-known works, taken together, is that they stress almost with increasing emphasis that the interpersonal theory of illness, or the interpretation of schizophrenia given by Fromm-Reichman, or the responses of patients to milieu reported by Stanton and Schwartz record the levels of personal communication as functions of both longstanding illness processes and more contemporaneous experiences. Although the parallel literature from group psychotherapy is too extensive and scattered to adduce here, group psychotherapists know that a particular "emotional climate" or discussion-sequence may modify individual and group interaction rates noticeably.

In the field of small group research, rate is the *quantity* or *amount* of human, symbolic interaction. We already know this quantity, as a total, is increased in the group process. However, besides the quantity or amount, there is the further question of the quality or depth of expression. In the three volumes mentioned, it is stated both theoretically and concretely that *quality* or *depth* of expressive communications may range from superficial to highly expressive symbolizations of subjective states. Small group research has often not troubled to make such distinctions as to content. Yet, in psychiatry, the quality or depth of the content of communications has been of overwhelming importance as soon as psychodynamics became a central focus of therapeutic procedures.

However, while amount or depth of communications has each been noted in psychotherapy, a third element seems to be involved if we are to deal with affective constants and variables associated with the terms we have listed. Both small group research, and considerations of the depth of expression, may easily overlook this third aspect. While the Freudian system suggests expressions in depth may be cathartic, increasing emphasis on ego structure has warned against an unbridled flooding of impulses. Much of this discussion has been couched in terms of transference and countertransference as if larger group relationships hardly existed.

The author, therefore, introduces as the third term the *emotional valence*, or *combining power* of an affective state, and of its verbal and non-verbal symbolizations. Here one thinks not simply of depth of emotion, but of characteristic style of affect. Polar examples might be hostile or cooperative utterances. But in reality, human behavior is so modified by symbolic constructs resident in cultures and in subcultures that no individual exposed to cultural backgrounds at all fails to incorporate emotional valences towards persons, objects and ideas. These are best called human *and* cultural values. Obviously, they relate to the social role expectancies and functioning of persons in a static or in a changing cultural scene. Equally, the social roles and statuses are themselves dynamic and multiple since they apply throughout the life-cycle.

To illustrate, in a scale, one who has participated in group sessions can discern the illness polarity in low rates of interaction as to quantity, depth or emotional valence. Actually, these aspects interblend or interpenetrate, affecting one another. For example, low rates of interaction may be mixed, or modified by, hostile non-verbal communications. As is known from studies of schizophrenics, the rate of interaction should not be confused with lack of reaction. Blocking, rigidity and withdrawal may all be defenses changing interaction rate. Similarly, on the levels of depth of expression, these impediments may be patterned or sharpened as habitual response to be denial, circumstantiality and only superficial contact with the tests and identifications of reality. Then, indeed, one is contrasting this lack of realistic spontaneity with forms of participation that are emphatically sincere and honest. Here we have been thinking of quantity and depth, respectively, in interaction processes. For the third term, emotional valence or style, the illness polarity may disclose, for example, generally antagonistic, resentful or revengeful modes of interpersonal expression as typical. Quantity, depth and style (or emotional valence) are, taken together, indices of the dynamics of an illness; and without this methodological organization or specific type of recognition, they have already

been utilized in successful individual or group psychotherapy.

In respect to the interrelations of these elements, we have already noted that quantity *increases*, in affective stimulus or response, mark both the normative and the therapy group. Why is this? First of all, the affective stimuli are increased by the presence of several persons, but in addition, Borgatta and Bales learned that an individual typically tends towards his maximum rate of participation, modified for each by respect for the participation of others(2). In such striving behavior, there may be attempts at mastery, coping or reward-seeking since Keller found experimentally that those who initiate more discussion usually have more remarks directed to themselves(6). One learned also by experiment that groups arranged in circular (democratic) and intimate face-to-face patterns, without intermediate dominating figures, had both more interaction and superior morale as a result, Bales adding to this that the optimal size is the 5-person group. Miller has noted in the same context of small group research as Bales(5) that there are limits to our natural capacity for processing information, and that 5 to 7 units mark limits for visual and tonal stimuli, beyond which, at 8 or more, errors are common. (Compare 1 and 8.) Like the "span of immediate memory" or digit span tests, 7 appears to be a common limit.

In anthropology, both Murdock(9) and Lowie(7) have noted the universality of the "nuclear family" of parents and children, with kinship systems beyond this unit ignoring, restricting or creating and expanding such natural bonds through terminological notations. The nuclear group terms, however used—and the systems are several in world history—seem to run parallel to what is learned as to optimal size of human small groups though the actual individuals noted may far exceed the denotative kinship calculus used to categorize them. These data on human social organizations corroborate Bales' experimental data on the "best" size for maximizing interaction, except that here social organizational realities require humans to apply denotative kinship terminologies to often vast groupings, like clan relatives,

which exceed common intellectual capacities.

In group psychotherapy, one is dealing neither with normative family structures nor kinship variations. Even the abstractions of normative group processes, their quantitative and interaction findings must be taken together with considerations of the depth and style of individual communications as affected by group process or milieu. Thus, depth and emotional valences become somewhat more germane than the quantitative matters just reviewed. As with kinship systems in culture, though there are quantitative parameters indicated by the human limits for processing information, the information itself must be processed in patterns that are both personally and socially meaningful to the individual, or they become lost items in the business of living. In the serious work of role-playing, we can only assume or interpret roles that have some symbolic meaning and significance. As participants in any settings, group-oriented or individually expressive, role-conflicts are bound to impede action, emotion or cognition where they proceed from a splitting of values, meanings and goals. Both neurotic conflicts in which the struggle for a meaningful integration is still going on, and psychotic splits in which roles are curiously divorced from realities express the resultant states, the balances and imbalances, achieved in the service of role conflicts.

Group psychotherapy, according to Dreikurs, developed "almost incidentally" within psychiatry as a form of treatment devised "primarily to save time for the overburdened practitioner(4)." This is true, but almost equally there was a sense of generic similarity in problems of role functioning of classes of patients. Pratt, designated by some as "the father of group psychotherapy," discerned near the turn of the century a common problem in lower class tubercular patients connected with the isolation and sense of secrecy and shame connected with this disease, and its recognition and management. Accordingly, he used the group technique to create hope and give patients instruction about the management of tuberculosis. In the mental hospital, both Lazell and Marsh suggested total push methods in application to

schizophrenia, creating awareness that psychotics received benefit or "revival" from social interests and responsibilities. Adler applied the method in a more preventive sense to teacher and parent groups, again social role categories. (Compare items under 14, Pratt to Adler.) There is no doubt that current group psychotherapy in mixed groups has moved from these basic considerations, but it is as concerned today with role-conflicts exhibited within individuals and in groups as it ever was.

Dreikurs, in the article alluded to above (4), claims the "First Psychiatric Revolution" occurred with the introduction of humane treatment in mental institutions. The "Second, or Psychoanalytic Revolution" may be designated in his fashion as stressing early development and family experience (our emphases, M.K.O) in an era of "accentuated individualism" during which the psychiatrist "moved into private practice" (Dreikurs). Whichever aspect one stresses, the role of the physician, or the tendency to extend the interpretation of human relationships in the light of the patient's experience in the family, the latter were, as Dreikurs has noted, explored chiefly through individual psychotherapy following the recognition of the dignity of the person. It is easy to underestimate the importance of the psychological development of the individual in a family setting. In terms of our own methodological organization, we may note that the current emphases on small group dynamics—the typical sociometric and quantitative approaches to interaction—equally underestimate roots of family settings in typical subcultures of our times. While the quantitative approach to interaction may recognize human limits and potentialities for communication, such discussions of human optimum capacities are abstract unless both family and cultural role conflicts are explored. It is no accident that while group psychotherapy left the door open for Freudian and Neo-Freudian experiments in the quality or depth of expressive communications, it said less about emotional valences or basic styles of affective role conflicts.

However, besides the individual and the

group, and the concerns respectively for depth of affect and quantity of interaction, there are the affective patterns or styles of emotional expression which are chiefly an outcome of cultural role conflicts. Anthropology has long recognized these, without systematization in any given theory of personality, under the rubric of *acculturation*. The author, in working with Linton, and in focusing upon acculturation differentials where two cultural groups were involved in cultural change and interchange, noted in 1940 that larger cultural conflicts disrupting integration within a group resulted in poorer health, mental and physical, for the more rapidly changing culture representatives (10). This position was expanded in the framework of personality theory, in 1956, to include the nature of the culture, that is, its roles and role-conflicts in the setting of the pace and type of acculturation which existed. (Compare items, 10.) Just as *depth* of affect, a function of the quality of defenses, may govern the *quantity* of interactions or communications, so the experiences of early learning, affecting this depth, may influence the individual rates of response, in one direction or another. This formula states, in effect, that family experiences are crucial in determining what Chapple designated as normative interaction levels. Genuine group experiences, in 5-8-person groups, are apparently maturing or socializing in this sense since they provide the setting for normative levels to emerge while providing, even more than in individual therapy, the various parental, sibling and child surrogate figures which so often appear in such milieus. Consequently, when properly organized, they raise interaction rates on the average. It is presumed, when such symbolic substitutions for family figures are made, or when transference and countertransference phenomena occur with greater rapidity, that an advantage is gained by such symbolic introductions of family figures and amnesic experiences. No doubt, this is not only because quantitative rates are increased, but because *depth* and emotional *valence* or *style* are more involved. In the author's terminology, one is introducing the *wider context* and its *bind-*

ing conditions into the stage of affective recognition by inducing the patterned family and social influences (11).

These patterned family and social influences, to the extent they are acquired or transmitted by symbols and express roles, are by definition cultural. Since value orientations and motivational structures meet at this point, depth and style likewise converge. In dealing with symbolic, culturally influenced roles, psychiatry will do well to recognize that such behavior depends upon patterns larger than specific family contexts, but are ingrained and reinterpreted chiefly through family settings. The psychic economy requires some perceptual, affective and cognitive classification and denotation of experiences, much as kinship system, language structure, or ethical and valuational methods in a culture provide the simplifications that allow us to read the social and cultural map. Thus the individual products of any social and cultural influences are not coterminous with the adjustments found in society and culture generally, and we may speak of the uniqueness of an individual or the variance within an illness process. The limits to individuality or even "normalcy" for that matter are set by common experiences in family and extra-familial settings. Because social roles are limited by life-course associations, speech patterns, or styles of emotional expression, they are undergirded by value systems, motivations and culturally determined stresses. In addition to depth of affect, we can ignore style of emotional expression and role-conflicts only at our peril in psychotherapy. Both influence quantity and depth of emotional communications. In short, the wider context of emotional valence and culturally determined roles influences the depth and quantity aspects of psychopathology.

Because of space limitations, only two examples may be given. A Puerto Rican psychiatrist, Torres-Aguilar, reports his observation of relatively high prevalence of catatonic outbursts of a hostile and aggressive sort in schizophrenics of lower class background. Schizophrenics with paranoid reaction, centered in confused sexual identity, are likewise typical and the paranoid elements are freely

expressed. In the neurotic categories, classical hysterical conversions, attacks of fainting more commonly for women, and freely expressed hypochondriachal complaints seem more marked in urban Puerto Ricans of the island than in most modern cultures. Today, such traits are seldom emphasized in reports from other urban scenes. Our observations on Puerto Ricans on the mainland, first generation, run strictly parallel. In fact, all norms of emotional expression and display of affect are more noted among these people. There is, as a cultural pattern, little inculcation of guarded affect, an emphasis upon *soma* and interest in sexual detail, great concern about health, and currently much disturbance occasioned by a shifting, particularly in urban scenes, of the social and economic role positions of the two sexes. Dr. Torres' (15) and our own observations run parallel on finer details than can be given here.

Similarly, the author studied South Italian and Irish schizophrenics of 3 generations. The Italian migrants and their descendants appeared to have a larger proportion of patients having catatonic outbursts of the hostile and destructive sort, while the classical reactions of paranoid type were found in the Irish patients, varying considerably from Puerto Ricans in guardedness, for one feature. All had the "official diagnosis" of schizophrenia, but the differences were vast indeed. In discussions with such patients singly, or even in group situations on the ward, it was helpful to anticipate such variations in emotional patterns and discuss them with the patient on neutral grounds of cultural affiliation. Viewing quantity, depth and style of emotional communications as an integrated balance of personality, one avoids a moralizing, condemnatory or judgmental tone in favor of satisfying discussions of social and cultural roles. The neutral grounds of cultural interest and affiliation provide the wider context of family background and individual experience. Elsewhere, we have called this method of inducing the wider context as the initial step, "cultural push therapy" (10).

In our experience, cultural reference al-

lows for a more delicate processing and ventilation of experiences in therapy. The neutral grounds of cultural interest provide more motivation for achieving perspective on social role positions. Any relationships, going in a series from man to fellow-man (social relations), man to family, and finally degrees of self-awareness, figure in cultural discussions. Even man-to-nature relationships are relevant. Ordinary guide lines of cultural experience give perspective and provide the same life-course phenomena and family roles that are the typical interest of patient and therapist alike. The therapist's acceptance of a person's culture is therefore the first step in his understanding of the family and the individual. For the patient, similarly, self-esteem and self-awareness may well depend on the rapport set up in such interchanges of cultural meanings and implications. In the studies of schizophrenics, Italian and Irish, alluded to above (12, 13), the entire structure of the illness and of current defensive balances depended upon the emotional valences built up in a sub-cultural setting and in a family over time. Quantity and depth of emotional communications varied notoriously with the course of illness, but style of emotional expression, far more crucial, varied with the culture and the role conflicts introduced between generations.

In group psychotherapy, there is opportunity *par excellence* to build up cultural awareness and respected identities. These, in turn, represent a gain, or the occasion, for developing individual perspective on self-images, and empathy for the products of others' lives. For the therapist, who must guide the total process, an awareness of the differing family structures and role conflicts of various cultures and subcultures will provide a key to emotional valences of persons coming from various backgrounds.

Apart from quantity of human interaction, the varying depths and styles of emotional expression point directly to typical roles, which need better understanding and depiction, since these roles, in turn, represent the sorting into modes of action of values, aspirations, motivations and typical stresses. The firm texture underlying conduct is far from biological need alone. Until such keys to behavior, normative and aberrant, are used, we cannot enter into a world of meanings which are otherwise only the sealed-in aberrations of troubled minds.

NORMAL DEVIATIONS FROM REALITY

CLAUDE C. BOWMAN, PH. D.¹

"Reality" is a very ambiguous term, one that immediately raises a host of issues. Gregory Bateson has contributed to clarification here by outlining 5 definitions that can be found in psychiatric thinking(1). In one sense the word denotes the external world as perceived by the senses. This definition contrasts reality to fantasy and projection, but the term is often used in a contrary manner to denote the very subjectivity that is rejected by the first definition, reality referring to the individual's private world. A third definition involves awareness of one's idiosyncratic views and an ability to transcend these individual peculiarities in the interest of greater accuracy and effectiveness. Fourthly, the word appears in the phrase "the reality principle" which is commonly contrasted with the "pleasure principle," thereby suggesting that reality is unpleasant. Finally, reality is often contrasted with phenomena of magic. In this sense it is based upon the conceptions of science.

The relevance of these 5 definitions to the means and ends of psychotherapy is a complex subject that lies outside the competence of the sociologist. Here our purpose is to show that certain degrees of unreality, far from being a handicap to normal men and women, actually contribute to the maintenance of their morale. We shall maintain that the biases favorable to morale are not occasional deviations from normal thought and action but are in fact indigenous to culture and social living.

Now it is evident at once that a particular definition of reality is implicit in this statement of purpose. Let us be more explicit. In the discussion that follows a *sense of reality refers to conceptions of the social environment and of oneself which satisfy the highest standards of objective accuracy.* It may be noted that this definition touches upon the first, third and fifth definitions developed by Bateson. From our point of view realism stands in contrast to the conventional biases and illusions of man's social life.

¹Department of Sociology and Anthropology, Temple University, Philadelphia 22, Pa.

Immediately the question will be asked, "And who shall decide what is objectively accurate?" Are we not hopelessly caught in the toils of biases both subjective and collective? Actually the dilemma is less formidable than might seem to be the case at first glance. Once the fundamental value of special competence is granted, it becomes relatively easy to establish adequate standards in the complex task of determining reality. An assessment of sociological data and of opinions about these data can be undertaken by scientific experts whose knowledge and judgment tend to approach objectivity. Just as the psychiatrist possesses special competence in judging degrees of reality or unreality in the patient's mind, so the social scientist is equipped to determine not only the nature and extent of distortions in collective thought but also their social causes and effects.

The following examples represent common types of deviation from reality that can be found in American society today. Of course, it is not suggested that *everyone* exhibits these tendencies, but merely that the types of thinking described here are sufficiently common to warrant the attention of the sociologist

NATIONAL CULTURE

The concept "ethnocentrism" serves to emphasize the amount of unreality existing in all cultures. Each folk or nation tends to consider its ways as best and measures other cultures by its own yardstick. The achievements of the past, the rightness of current practices, the greatness of their destiny—such grandiose views are widely supported by the members of a given society. Informal and formal teaching by adults give sanction to the *mores* and this process of indoctrination is reinforced by habits formed in the daily round of activities. In a sense it may be said that, when one member lies—in an approved direction—the rest will swear to it. Thus, each culture generates and preserves a set of biases considered appropriate to its

ongoing life. The "strange," "irrational" or "immoral" ways of other people are viewed with amusement or alarm by the vast majority who, by these reactions, give emotional sanction to accepted patterns of living. Even in the most liberal cultures open-mindedness in regard to basic *mores* is sometimes tolerated but never actively encouraged. Australian aborigines, Japanese, Americans, and all other peoples are expected to follow the fundamental beliefs and values of their respective cultures.

Except during periods of upheaval and rapid change, deviations from cultural orthodoxy are not frequent enough to constitute a serious threat to group integrity and morale. The majority have little desire to run athwart the conventions but grow up to believe what they are supposed to believe. Some sacrifice of reality seems a small price to pay for social approval, especially since most people do not understand obscure issues of reality and unreality and, consequently, are wholly unaware of any "sacrifice." It is true that the more democratic nations do permit critical public discussion but even in these countries the distorting influence of patriotism is quite evident.

The following illustrations bear upon this point. We in the United States want to believe in the essential soundness of our family system, business institutions, schools, system of government, and our other institutions. Out of this patriotic faith the citizen builds loyalty and morale for peace-time pursuits as well as for times of war. It has come as a shock to many to learn that the "backward" people of Asia believe that they are just as important as the United States of America. In our naive way we tend to think that everywhere the world over accepts the goodness and greatness of our country as a permanent feature of the universe. We firmly believe that our actions are ever rooted in high moral principles and feel hurt or irritated when our policies are examined by other countries for dollar diplomacy. Moreover, when certain powerful leaders of Asia prefer to avoid clear-cut alignment with our side in the cold war, we tend to react with adverse criticism, if not open denunciation. In such ways patriotism may preclude an adequate apprecia-

tion of the problems of Far-Eastern countries.

On the domestic front one of the most noteworthy examples of unreality is the refusal of the general public to face the grim possibilities of war. A naive observer, uninitiated in the processes of illusion-building, might surmise that the development of atom and hydrogen bombs, not to mention bacteriological warfare, would lead our nation to give this problem top priority. But what has been the situation during the post-war years? Civil defense gets small public attention and small public subsidy. Urban re-development proceeds largely on the basis of pre-atomic thinking, increasing congestion rather than encouraging wider dispersal of the population. And what of the private efforts of individual families? Conscientious parents, striving to establish a good home for their children, will look amazed when you ask whether they have made plans for protecting their families in the event that a major war should break out. It is just too horrible to think about.

This is conventionalized escapism, to be sure, but it is the present thesis that such deviations from reality are important to adjustment. What can the individual citizen do, in the face of technological progress and institutional lag, except to indulge in a certain amount of "ostrichism?" Somehow or other he must carry on his daily affairs as if such threats did not exist. Perhaps physicists and engineers are perfecting a bomb five hundred times more destructive than those dropped on Japan in 1945 but right now the baby must be fed, the boss is calling for that report, or a party is being planned. The maintenance of morale seems to require that we avert our gaze from the grim possibilities of destruction, and hope for the best.

It is clear that the optimistic spirit has pragmatic value for individuals and groups, signifying faith in purpose and expectations for success. Yet optimism operates as a defense mechanism, the optimist seeing only what he wants to see. Aspects of the total situation that do not fit his orientation are ignored or, if recognized dimly, pushed aside before they emerge into full consciousness. Those holding important administrative positions may expect subordinates to discol their

doubts. Others seek reassurances from family and friends. In numberless ways we support each other in rose-colored views of reality and express disapproval of those who try to puncture the illusions by which we live.

The origins of American optimism must be sought in history. This frame of mind developed readily in a new country, rich in natural resources, expanding industrially and agriculturally, growing in size and power as more and more young, ambitious immigrants came from Europe. An optimistic outlook was an essential ingredient of the enterprising spirit of the 19th century and many believe that it is just as essential today.

SPECIALIZATION

Some degree of distortion appears to be inherent in the outlook of the specialist; indeed, in folk humor, specialists of all kinds are belittled because of their biases and lack of common sense. Now the sociologist realizes that various institutions (economic, political, educational, religious, recreational, etc.) in modern society are characterized by an increasing proliferation of structure and function, leading to individual careers which are more and more specialized. Yet, in the midst of this growing division of labor, the individual tries to preserve a sense of his significance and worth. In some occupations, such as routine tasks of a large factory, it is difficult to do this; but even in careers of higher status there is a constant struggle to preserve a sense of personal significance. In this effort a full and steady sense of reality may be a distinct handicap.

The academic profession may be used as an illustration. As subject-matter in various fields of knowledge has broken down into more specialties, scholars tend to concentrate upon knowing more and more about less and less. Under these circumstances it is easy, and perhaps necessary, to over-value the particular segments of knowledge where one's own proficiency lies. Such over-valuation seems integral to professional adjustment in the academic world as it exists. He who plays the game according to the rules is likely to gain promotions, offers from other institutions, an impressive list of publications, and other advantages. College presidents may deliver stirring addresses criticizing the narrow

specialist, and a few professors, particularly in obscure colleges, may resist the trend but these instances have little effect upon major tendencies in the academic profession. (In a few universities the embryonic professor can now take broader graduate programs in the social sciences or humanities but it remains to be seen whether this type of curriculum will have a significant impact upon Ph. D. education.)

It is the function of college administrators to construct a broad overview of institutional purposes. Insofar as administrators fulfill this function, they do bring a more realistic perspective to bear upon major decisions, decisions compounded of many ingredients contributed by various specialties both within and without the institution. Yet it cannot be assumed that top administrators are consistent realists. The ego feelings of these leaders are likely to be deeply involved in their organization. Such persons look upon the enterprise as peculiarly theirs; its successes and failures are felt more keenly, its good name is related to personal pride, and faith in the institution is an extension of the leader's faith in himself. Thus, the typical college president wants to believe that the collegiate *status quo* is essentially sound. "Our college is doing an excellent job, the faculty is capable and contented, the students eager and appreciative," he tells himself optimistically. Like other practical men of affairs he accepts the reality principle only so far as it is practical to do so.

Higher education has been used as an illustration but the same processes are evident in other fields. Within the professions there are at least 3 conditions leading to occupational bias. 1. A long period of preparatory education, involving time, effort, and money, leads the professional person to place a high valuation upon his achieved proficiency. 2. Colleagues in the same field tend to support each other's evaluations and rationalizations. 3. Professional organizations also contribute to morale by holding conferences and performing various rituals designed to give further sanction to group purposes. If, out of this multilateral process of indoctrination, the individual begins to magnify the importance of his chosen career, it should occasion little surprise.

SOCIAL CLASS

A common illusion is that there are no social classes in the United States. Many like to think that one person is just as good as another in this democracy where "all men are created equal." Now it is true that social stratification in this country does not consist of historically fixed categories sharply separated from one another by insurmountable barriers; instead, we have an "open class" system. Nevertheless the factor of status is very important in social relations. Groups on a vertical scale show relative differences in manners, morals, material comforts, occupations, residences, and civic participation from those of a higher or lower status. For this reason we may properly speak of class sub-cultures.

People of various social levels tend to develop and defend an outlook on life that is functionally appropriate to their particular position. Some in the highest strata hold to the complacent opinion that the cream of society inevitably rises to the top, ignoring completely such influences as family background and inherited wealth. That broad segment of society known as the middle class commonly considers itself to be the salt of the earth. These people assume that all "sensible" folks think as they do about politics, careers, family life or education. The lowest strata also have their special ideological slants. The rich and powerful are "lucky," the poor "unlucky." Some will even assert that the higher classes operate on a lower moral plane while they are "poor but honest." To be sure, such face-saving rationalizations may contain elements of validity—but elements of unreality too.

Since the class-bound person seldom carries on extensive communication with those of a higher or lower status and since most of his associates are also class-bound, he finds it easy to retain these parochial views. In this way certain distortions are supported by the various classes—with favorable effects upon morale.

MINORITIES

Racial and national minorities may also show a reluctance to face reality. An ambitious Negro may insist upon believing that

"there is plenty of room at the top," minimizing the handicap of prejudice. And why not? Assuredly it is not practical for him to dwell upon such handicaps. Similarly, Jewish men and women sometimes wear blinders so that they will not see anti-semitism. Indeed, some are sharply critical of other Jews who insist upon taking notice of prejudice. Again, in the interest of morale, why look unpleasant reality squarely in the face?

LOVE AND FRIENDSHIP

Through the ages it has been said that love is blind. Today it is fashionable among family sociologists to decry romantic illusions and urge a more realistic point of view. To some extent the new realism is salutary, for it represents the substitution of informed intelligence for traditional ignorance and mysticism. Yet the dynamics of teachers and textbook writers who criticize romanticism will bear further scrutiny. Perhaps the disillusionments of middle age are involved here. Also, a puritanical value system may lead such persons to emphasize the gospel of work and, correspondingly, to distrust those pleasures that detract from the serious business of "getting ahead."

From whatever sources it arises, this "realism" fails to understand that, in heterosexual love, the reality principle is at times "more honored in the breach than in observance." The dependent person, seeking security in the love of another, may magnify the other's strength and dependability because of this inner need. Other idealizations may concern beauty or achievement or ethics. These elements of unreality are not necessarily harmful; in many instances they are distinctly advantageous to both persons.

Parental conceptions of children can be equally unrealistic. Parents often have exaggerated notions concerning the capacities and achievements of their children—as every teacher knows. Conventionally we come to expect a certain amount of illusion on the part of parents, and even view it sympathetically. Of course, there will be disappointments when such conceptions depart too far from reality but, within limits, sentimental biases constitute a bond of cohesion in family life.

On a lower plane of emotional attachment the same principle is evident in friendships. We tend to be somewhat unrealistic about good friends, thinking the best of them and criticizing those who criticize them. Perhaps many of us play politics where friends are concerned; we recommend them for positions because we like them and not because they are, in the cold light of reason, the best qualified. Such biases are given open approval in a culture that stresses the value of friendliness.

At the same time friends are expected to contribute to one's own morale by praising achievements and minimizing failures. In this way favorable self-conceptions are maintained and the harsh impact of reality softened. Thus, it may be said that a person's friends are part of a pleasant conspiracy to keep him in good spirits.

SELF-CONCEPTIONS

This leads to a final word about self-attitudes and mental health. According to the definition given earlier, realistic appraisals of one's self are based upon objective assessment of a whole range of relevant factors. On the other hand, the maintenance of morale may require some degree of emphasis upon ego-gratifying factors in the total situation of the person and a minimizing of ego-

deflating factors. Such selections and rejections are made continually by the healthy-minded individual. Unconsciously perhaps, he gives goals of happy, effective living priority over the demands of strict logic.

It may also be asked to what extent these morale-building biases are encouraged in the course of psychotherapy. This is a complex question with many ramifications and, in all probability, different kinds of therapists would give different answers here.

SUMMARY

The foregoing discussion is concerned with normal deviations from reality in contemporary social life and the useful purposes which these serve. The author is not in agreement with those who believe that good mental health must be based upon realistic conceptions of environment and self. It is the present theory that individuals and groups normally develop biases consistent with their standards and purposes. This tendency involves elements of unreality but it favors mental health and high morale in society.

RELATIONSHIP BETWEEN SOCIAL ATTITUDES TOWARD AGING AND THE DELINQUENCIES OF YOUTH¹

MAURICE E. LINDEN, M.D.²

INTRODUCTION

It must be stated at the outset that in effect this paper adds another imponderable to already extensive lists of factors contributing to youthful misbehavior. It is to be hoped however that it will not be classified in that group to which Edwin J. Lukas(1) refers when he states, "Each so-called 'preventive' enterprise has its own concept of causation to which it adheres with a tenacity which would evoke more admiration if the concept were more valid."

At the risk of oversimplifying a serious and complicated field of inquiry the writer is emboldened by a group of observations having a uniformity that urgently suggests they may well be facts:

1. Certain social changes predominantly in western societies have taken place during recent decades which constitute a shift in emphasis toward children's needs, resulting in the 20th century's often being referred to as "The Century of the Child"(2).

2. Concomitant with unprecedented population increases in the late mature categories there is abundant evidence of increasing dependency by the elderly upon public institutions, often associated with diminishing acceptance of family responsibilities toward the elders. A factor of elder-rejection plays a prominent role in such transfer of obligation (3).

3. Psychiatric clinicians have noted a widespread fundamental change in the clinical picture of the neurosis, with diminishing numbers of the classic neuroses but an overwhelming increase in character disturbances in which "personality" and "symptom" are practically indistinguishable(4).

4. Increased attention in Western culture during recent years has been drawn to the problem of youthful misbehavior. The Di-

rector of the F. B. I. in the United States has issued a public statement to the effect that there has been a definite increase in juvenile delinquency rate disproportionate to population growth.

5. There is fair evidence that countries and ethnic groups having a low juvenile delinquency rate are those whose cultural atmosphere reflects veneration and, or at least, acceptance of the aging and the aged. Agreement is general among sociologists and anthropologists(5) that elder-veneration, tradition-boundness, and a low rate of youthful delinquency are frequent concomitants.

The present thesis suggests that the foregoing social findings are mutually interrelated in a psycho-social equation; that a cultural factor of elder-esteem or elder-discard enters intimately into character formation in the development of personality; that the characterological attributes having to do with attitudes toward the aging are decisively linked to value systems governing moral and ethical principles and conformity; that devaluation and discard of the late mature generations are real social hazards potentially damaging to children; that the absence or distortion of a concept of social authority in which the status of the elder plays a significant role contributes importantly to a widespread looseness, waywardness, and rebelliousness of youthful behavior; and that without losing any recent social gains it is possible to influence favorably some aspects of the character formation of youth by restoring to the process of aging a connotation of authority and an implication of social reward.

THE CENTURY OF THE CHILD

Today the long overlooked needs of children have begun to receive attention. What is often forgotten, however, is the tendency of human nature to overcompensate for its defects, and to concentrate with almost fanatic enthusiasm on newly uncovered areas

¹ Presented at the First Pan-American Congress on Gerontology, Mexico City, September 18, 1950.

² Director, Div. of Mental Health, City Hall Annex, Philadelphia 7, Pa.

of social omission. The unfortunate consequence is the impoverishment and neglect of other sectors of social endeavor.

There is abundant evidence that the qualities of youth are the preponderant social goals. Note the prevalent anxiety regarding chronological age. Witness the omnipresent emphasis on newness, sleekness, freshness, mobility and change. But, in particular, observe the everyday tragedy of people moving blindly toward the later years with their inner vision arrested deceptively upon a fond mirage of the irrecoverable past.

Mankind hardly deserves any kudos for protecting and guiding its own helpless developing neophytes. Such are the functions of inherent biological drives. But the severe test of a civilization is found in its capacity to advance beyond the simply biological, and to create systems of group living in which personal welfare and meaningful existence are every participant's birthright.

We cannot escape the present reality in which the qualities of the young side of life are upgraded.

ELDER-REJECTION

Today more people remain healthy, live longer, and reach later maturity than ever before in history. The implication of social progress is tempered by certain other parallel disturbing facts: the tremendous number of older people for whom admission is sought in mental institutions; the mushrooming nursing home enterprise; the immense proportion of elderly on public assistance rolls; the widespread absence of social and recreational provisions for older folks; the marked increase in hospital occupancy by the chronically ill; the large numbers of solitary and bewildered aged existing in substandard living conditions, passing time aimlessly awaiting the end.

Certain exigencies of urban living plus a deep psychological predisposition to regard aging as unattractive(6) have forced ever greater numbers of families to relinquish a time-honored responsibility and divest themselves of the duty to care for their older members. The closing decades of the century may mark the *Era of the Nursing Home*.

That the windup of a life in the segregated quarters of some types of institution constitutes an empty and uninspiring goal can hardly be questioned. And there is logical foundation for the conclusion that all forms of social and psychological rejection of the elders are incorporated in the self-concept of the aging and eventuate in self-rejection that heralds personality regression and disorganization.

More important still are the effect of attitudes on the character development of oncoming generations.

CHARACTER DEVELOPMENT AND DISTORTION

The formerly common classic neuroses, such as hysteria, obsessional and compulsion neurosis, were based on rigid prohibitions, suppressions and extravagant punishments. It has been said(7) that "the inconsistency of the modern neurotic personality corresponds to the inconsistency of present day education. The change in the neuroses reflects the change in morality."

Character may be defined as an individual's habitual mode of responding to demands from various sources within and without the psyche(8). It is socially determined(9). The concept of character is closely analogous to the concept of "ego" as formulated in modern psychiatry. The ego has many functions, among them being the mediation among the demands of the instincts, the pressures of conscience and certain internal automatic repetitive tendencies. Even in greater measure the ego, or character, is called upon to integrate intimately into its structure the innumerable surrounding social stresses including the mores, ethics and group attitudes.

Uncomplicated observation suggests that the perpetuation of social and cultural values, the development and support of moral and ethical judgments, the evaluation and maintenance of the substance and resources of knowledge, as well as a related assortment of intellectual activities are the inherent functions of the mature mind. Man's concept of God and his ideal representation of the elder are the authorities for systems of discipline. They serve also as the source of power and impetus to effect a realization of social plan-

ning, to create and maintain systems and modes of social welfare, and to preserve the thread of philosophical continuity that runs through the basic principles of a civilization.

The development of an ideal social conscience in a child is consequent upon the success of psychological mechanisms through which he incorporates the best personal and social symbolic images available for identification. The inspirational goals that antecedents personify and the regard of the child for his elders figure significantly. The child also will absorb the inconsistencies, the unsolved problems, the prejudices and antipathies of his educators. As Johnson(10) has pointed out the child incorporates into his character factors operating from the unconscious structures of the minds of his educators.

The maintenance of the parent and grandparent ideal as the source of wisdom, goodness and love, judiciously associated with adherence to principle is significant in the creation of an ideal social character in the child. The socially oriented structure of his character becomes weakened if there is need for rebellion against his educators. In most individuals rebellion against the elders represents a seeking after independence and personal expression. In an ideal society, regardless of individual rebellion, an aura of respect for the elder and elder authority would remain constant.

The social inconstancy of parental character, a cultural rejecting attitude toward older people and a generalized mitigation of their social authority are readily absorbed in the character formation of the developing child.

The older generations, by virtue of psychological and physiological aging processes, cannot long endure the pressures of downgrading and hostility to which they may be exposed and their diminishing resistance may progress toward social powerlessness. Such debasement of the elder in the role of and as the symbol of authority tends to diminish the meaningfulness of all social authority. Youngsters may then incorporate into their own character an attitude of regarding aging mainly as decline, decrepitude and loss of purpose. When this happens, the child may

establish himself in his own eyes as a potent and autonomous authority.

YOUTHFUL MISBEHAVIOR

The decline in parental influence which parallels the decline in social authority of the older generations is currently reflected in a widespread need for an increase in police authority. That is, wherever family control is weakened, society finds it necessary to increase public and impersonal methods of behavior control.

This is not the equivalent of judicious parental control. Policing agencies are generally regarded as restrictive and punitive, not as loving guidance and training agencies. The immature character finds the presumedly punitive agencies challenges for rebellious and hostile acts. Thus, what in ideal family life would be beneficently controlled rebellion, in the social setting becomes open conflict.

Since policing services are looked upon as law enforcement instruments the distorted character's behavior may tend to avoid only that which is illegal in order to remain clear of the law. Such technical conformity permits a great latitude for actions that are socially opprobrious but not strictly illegal, and nefarious and discourteous practices of all kinds become an increasing reality. There is real social danger and potential damage to children in a social setting that demerits the elders.

Impressionable youth lacking adequate older objects for consistent identification may develop an enormously exaggerated belief in their own capacity to destroy tradition. They may disregard the mores, flout ethics, and discard historically established qualities of discipline.

Statistical tabulation(11) of juvenile offenses reveals a high incidence of acts of furtiveness and stealth or incorrigibility and ungovernability. The minority of problems are in the area of passion or bold aggression.

An overdramatized and grandiose self-concept in the young contains the danger of contagion. The illusion of being "master" is communicable among the immature. It is a deception that may be basically responsible

for the revolutionary abolition of tradition by an entire social group and the acceptance, if even only temporarily, of a neo-devotion created on a substructure of personal aggrandizement, impulsiveness and hedonism.

ELDER VENERATION

A lack of leadership uniformity which seems intimately bound to degradation of the elders furnishes fuel for hot rebellion in younger persons whose drive toward unwise autonomy is thus reenforced. Within the family a set of attitudes is often created in the young as they observe the now hidden, now open, brutality practiced upon their grandparents by their parents. "As the child incorporates in himself the image of his parents as part of his internal organization he is absorbing among other things this very pattern of sadism against the senior elder. Thus is guaranteed the fact that the vicious cycle of elder rejection will remain unbroken generation after generation" (6).

Tradition-bound societies, some of which are exemplified in the ancient Chinese, Hebrew and Indian cultures, can boast of a low rate of juvenile delinquency. The common denominator in tradition-boundness is respect and veneration of the elders. A return to the "good old days" with increased irrational authority of the parents and elders, it is said, would help materially in reducing the psychological breakdown that eventuates in senility, as well as reducing the rate of youthful misbehavior. However, many social scientists and community leaders would decry any retrograde cultural change that would imply loss of any social gains enjoyed today.

Thus there is need for social planning so designed that the late mature generations are reassigned social recognition as well as the comforts and rewards to which human nature aspires.

Within the family the parents cannot relinquish their affectionate and responsible educative role without insidiously affecting the character formation of the young; and the foundation for good government and good citizenship is to be found in the proper structuring and functioning of each family.

If the hypothesis (12) is accepted, that

normal maturation into the later years means increasing altruism in the older mind, then it is possible to conceive of a society in which collective social authority is irrevocably linked with elder-veneration without the necessity for sociological retrogression. It is the very nature of benevolent elder authority to employ its power not to command and dominate, but to develop leadership among oncoming generations, and to serve as adviser, consultant and coworker.

CONCLUSION

In the awesome network of social forces that relate to character and behavior distortion the hypothetical factor herein presented concerns itself with but one thread, perhaps a guyline. There seems to be a commonsense logic in the viewpoint that degradation of the elder role-model of social authority is paralleled by an increase in arrogance and wilfulness in the young.

The fact remains that aging in our culture is generally unattractive and unrewarding. A newspaper supplement recently stated the case succinctly, "the world is made for youth and youth is the time for fun." Can we expect the young to make provident and prudent psychological preparations for the advancing years, when the later period is so often seen in threatening aspect.

Desirable character formation in the young requires that the group character of a culture present a social atmosphere of dignified elderhood in which symbolic authority is implicit, an authority enriched with warmth, humanism, and charity, yet firm in its leadership, independently motivated, and oriented around group principles.

Nature has endowed youth heavily with a capacity to achieve its own rewards. Aging needs social support. If the rewards of youth are to be wisely invested to insure that lives are well spent, then the elders must be reinstated in their time-honored position as brokers in experience and consultants in living.

AN ENGLISH VIEW OF AMERICAN PSYCHIATRY

MICHAEL SHEPHERD, D. M.^{1, 2}

"It has been difficult," said Dr. Whitehorn in his 1951 Presidential Address to The American Psychiatric Association, "for many European psychiatrists to understand the American situation(25)." He could not have meant to imply that they lack interest in the subject. On the contrary, during the present century the growth and influence of American psychiatry have so increased that to psychiatrists elsewhere a visit to North America has come to constitute an almost indispensable part of their post-graduate education. For financial rather than medical reasons it is unfortunately an experience which has been enjoyed by only a small minority, and without this opportunity the opinions of the European psychiatrist must depend on the conflicting reports of his more fortunate colleagues and on the torrent of American publications. Accustomed to a more centralised tradition of medical training and research, usually with the university clinic in the foreground, he is hard put to it to understand the many, diverse and possibly unfamiliar institutional forces—State supported institutes as well as university centres, federal agencies like the United States Public Health Services, voluntary organisations like the National Association for Mental Health, private hospitals and clinics and the great foundations—which influence the form and direction of American psychiatry to-day. Perhaps it is inevitable that many European psychiatrists, seeking for some uniformity amid seeming chaos, have tended to heed only the most clamant of many voices and have assumed, again in Dr. Whitehorn's words, that "... the psychoanalytic movement has captured American psychiatry."

Among the European schools of psychiatry that of Great Britain has a close traditional link with North America. Between the wars many of the most eminent British psychiatrists made their pilgrimage to the Henry Phipps Clinic, and Adolf Meyer handsomely

acknowledged the contribution of British to American psychiatry in the 14th Maudsley Lecture(20). Describing his impressions of North American psychiatry more than 25 years ago one British professor concluded that "... the future is more secure in America than in any other country(19)." More recently, however, there has been evidence of what another British professor has termed "differences ... of quantity and tempo" between the psychiatric developments in the two countries(17). Some of these differences have found clear and even sharp expression in publications from both sides of the Atlantic. Dr. Freyhan, however, in his recent sympathetic review of European psychiatry concludes that American psychiatrists are as likely as their European colleagues to be struck by the unfamiliarity of what they find on leaving home(12). Indeed, he goes so far as to stress Professor Bleuler's warning that a breakdown may occur in communication between psychiatrists on the two continents. Such a situation is unknown in other branches of medicine, and it cannot but be deplored. Dr. Freyhan's article also makes it evident that the best in European psychiatry is of interest to American physicians not only by virtue of its intrinsic quality but also because of the light it may reflect on domestic problems. Ample confirmation of his opinion was provided during the year which the author was privileged to spend as a Postgraduate Travelling Fellow in the United States,³ when many of these problems were frequently raised in discussion with American colleagues. The discussions proved invaluable for the purpose of clarifying many obscure aspects of American psychiatry; they also helped make possible the formulation of some general views about it. Incomplete as such views must be, they have been summarised here in the hope that one observer may have been able to see something of interest to the participants.

Many of the misunderstandings which

¹ The Maudsley Hospital, Denmark Hill, London, S. E. 5, England.

² Corresponding Fellow of the A.P.A.

³ Travelling Fellow of the British Postgraduate Medical Federation in the U.S.A., 1955-1956.

have arisen in other countries about American psychiatry spring from a failure to understand the social setting in which the subject is practised(15). It is widely recognised that the content as well as the form of psychiatric practice is moulded by environmental factors. This complex issue can be illustrated by reference to the distribution of psychiatrists working respectively in the public service and in private practice. In England psychiatry, as a branch of medicine, comes within the orbit of the National Health Service; the bulk of the working time of British psychiatric consultants is devoted to salaried service in hospitals or other public institutions and private practice must consequently assume less importance in the majority of cases(1, 21). The efforts of the British Ministry of Health to improve the quality of mental hospitals and to develop them as dynamic centres of community service have been dependent on a supply of well-trained and often highly qualified physicians; to them are due the more liberal use of voluntary legal status, the development of domiciliary consultations, and of out-patient clinics, the experiments with the "open door" and the "therapeutic community," and the emphasis on rehabilitation(7, 16, 18).

Medical care in the United States is organised very differently. Nearly 3,000 of the 7,500 recognised psychiatrists in 1951-52 listed private practice as their major activity(5). By 1954 Davidson has shown that the private practitioners for the first time outnumbered their colleagues in salaried positions; further, one-quarter of them were engaged exclusively in the practice of psychotherapy and were not considered to "... meet the traditional criteria of the practice of medicine(8)." (These figures, of course, take no account of the large number of non-medical psychotherapists practising in the United States, but they have very few counterparts in Great Britain.) It is thus apparent that proportionately fewer American psychiatrists are in salaried public service and their role and functions are correspondingly modified.

A trend of this nature has other implications. Since no form of medical education can be dissociated from the purpose to which it is being put, the organisation of psy-

atric practice patently exercises a profound influence on psychiatric training. At the present time it is difficult to avoid the impression that to a substantial number of young American psychiatrists several of the major professional incentives—public status, mode of living and financial reward—are associated far more with private practice than with hospital work. From years of experience with a residency training programme in Massachusetts, Barton and Yakovlev reported the "... reluctance of residents to accept even financially attractive appointments in the geographically isolated state hospitals and even in many of the training-wise self-contained institutions(4)." The specialist therefore understandably demands that much of the curriculum should be devoted to psychotherapy and psychodynamic theory. His relationship with his supervisor often constitutes the corner-stone of his instruction(23). Conversely, there is a distaste for the tracts of detailed knowledge dismissed as "descriptive psychiatry"; an antagonism to many of the facts and concepts associated with the study of heredity; a neglect of much biological investigation; and, as Kanner has so strikingly shown, in many centres a biased ignorance of the evolution and the historical roots of modern psychiatry(14).

To an English observer the problems and experiments in psychiatric education in America seem to be of cardinal importance. On the one hand he is impressed by the generous allowance of time afforded to psychiatric instruction in the undergraduate years and by the high status of the subject in many medical schools, even if he takes Professor von Baeyer's estimate of American psychiatry as "... Kommen unter den übrigen ärztlichen Disziplinen(24)," to be the comprehensible hyperbole of an admirer. Yet American views on the nature and purpose of psychiatric education are still conflicting and are sometimes uncompromisingly critical (26). The visitor is not entitled to pass judgment but he may legitimately ask whether the frame of reference which is most widely endorsed in many centres of training is broad enough to encourage the inter-disciplinary cooperation which is clearly needed for psychiatric progress. The dangers of a re-

stricted viewpoint have been illustrated in the past 3 years: the frosty reception given to the newly introduced "tranquillizing" drugs by psychiatrists with a bias against physical forms of treatment has been matched by the enthusiastic use made of the drugs by psychiatrists of a different persuasion(2). In many scientific fields work bearing on psychiatric problems has bombarded the clinical psychiatrist with data, theories and speculations, mined from the rich seams of the social and laboratory sciences, psychology, statistics and public health, to name only the more important. The contribution of the investigators in these fields constitutes the most hopeful and the most challenging feature on the American psychiatric scene: it demands continual assessment by clinical psychiatrists who are in danger of becoming passive, if receptive, junior partners in what should be a joint enterprise of collaboration. More is now demanded of the psychiatrist than a medical background, an administrative proficiency and a close acquaintance with one concept of individual psychopathology. "Research has become big business" according to the head of the Biological Sciences Division of the Office of Naval Research(22), and as very large sums of money become available, psychiatrists are being led or induced to assume a different role from that to which most of them have been accustomed.

Fortunately, there is no reason to believe that any single viewpoint can long dominate North American psychiatry. The 1956 centenary celebrations of Freud's birth demonstrated the high standing of psychoanalysis in the country but did not conceal the restless dissatisfaction which exists not only among the small number of avowed antagonists of the psychoanalytic movement(3) but also among its proponents. In Great Britain psychoanalysis has been in contact with, rather than a part of, academic psychiatry: its concepts have been transmitted through a semi-permeable membrane of critical examination and testing, and the rate of absorption has been slow. In the U.S.A. a remarkable attempt has been made in many centres to ingest the whole system, python-like, into the body of academic opinion. The post-prandial reaction seems now to be leading towards the elimination of indigestible matter and waste

products: in evidence are the pronouncements of leading psychiatrists like Whitehorn and Appel; the new stress being laid on the psychotherapeutic method as a research tool; the supplementary investigations of the psychotherapeutic process itself; and the experimental testing of many psychodynamic hypotheses, though for much of this work the credit must go to psychology rather than to psychiatry(13). It seems highly probable that what is of lasting value in psychodynamic theory and practice will find its way into both British and American psychiatry; the difference lies in the tempo, and in the route which is being taken.

There is, however, only a partial view of American psychiatry to be obtained from contact with the medical and allied professions. Since the early days of the mental hygiene movement psychiatry has entered into the fabric of American life in a way unparalleled elsewhere and which finds expression to-day in the widespread quest for "mental health." No one interested in mental illness can disregard "mental health" which, although it eludes all attempts at definition, remains a live and vigorous concept. To the visitor it seems that "mental health" would become a less nebulous objective if three separate uses of the phrase were always distinguished. "Mental health" is employed first as a euphemism for mental illness, and may as easily screen an inquiry into schizophrenia as into schools. Secondly, and more legitimately, it designates the campaign for the viewpoint of those workers who apply skills developed in the field of public health to psychiatric problems; workers for "mental health" in this sense concentrate on the group rather than the individual as the unit of study, conducting morbidity and other surveys and paying close attention to the principles of epidemiology and statistics. But in its third guise "mental health" can be understood only by identifying what one authoritative subcommittee has termed "... the flavour of morals and ethics, religious fervour, personal investment, unvalidated psychological concepts, value judgments, psychiatric theory, political science, welfare movements, and cultism(11)." It is more likely to be the task of the social historian than of the psychiatrist to analyse the full

range of "mental health" activities in America today. Meanwhile the sociologists have begun to clear the way (9, 10, 26). Psychiatrists should follow their progress closely if they wish to grasp the social implications of their own activities.

The signs augur a phase of self-examination and reassessment in American psychiatry. It is to be hoped that the forthcoming report of the Joint Commission on Mental Illness and Mental Health will indicate the direction which is to be taken. Whatever that may be, it is certain to influence those of us who work in other countries and who will hope to profit from the achievements and even the mistakes which will ensue. Meanwhile the achievements of British psychiatry in recent years testify to the progress which has been made and illustrate the shaping of many advances by social factors. No psychiatrist concerned with the welfare of his subject in either country can surely doubt that a closer professional and personal interchange will result in mutual benefit.

CORRECTION AND RETRIBUTION IN THE CRIMINAL LAW

LAWRENCE FRIEDMAN, M. D.¹

It is impossible not to sympathize with Dr. Richard Board's effort to establish a criterion of criminal responsibility devoid of moral judgement (*Am. J. Psychiat.*, 713:332, Oct. 1956). The approval which the article will doubtless compel from enlightened readers witnesses the shift of concern from judgement to correction that so regularly follows increased understanding. Different human interests make different uses of old institutions, and criminal jurisprudence is showing an undeniable tendency to regard itself as a doctor of society. In this role it will be assisted by Dr. Board's clarification of therapeutic rationale. However, psychiatrists have found by painful experience that advice is effective only to the degree that the advisor both understands the problem presented to him, and the perplexity from which it arises. It would seem that Dr. Board, in reflecting the new interest in correction, has permitted a certain relaxation of these requirements, and has overlooked considerations appropriate to his role both as psychiatrist and operational philosopher.

I

As a philosopher Dr. Board proposes that moral responsibility be discarded as a concern of the law because "moral responsibility [is] an idea having a metaphysical content dealing with free choice between the values of good and evil," whereas "the law constitutes an operation exclusively confined to the natural world of cause and effect." Though briefly stated and undefended, the first assertion is as controversial and unsettled as an assertion may be. It is familiar as the argument used by a group of critics to impeach the ethics of modern psychiatry. Psychiatrists, as good citizens, are wont to protest that the causal link between a person's actions and his total personality, far from excusing his behavior, is the prime requisite for attaching moral responsibility, which could not sensibly be attached to a freakish, spontaneous act totally unrelated to the personal-

ity(3). It is this fact to which Freud refers when he says "Obviously one must hold oneself responsible for the evil impulses in one's dreams. In what other way can one deal with them? Unless the content of the dream . . . is inspired by alien spirits, it is part of my own being"(1).

But if it is an error to regard moral responsibility as opposed to cause and effect, it is no less so to regard the law as "an operation exclusively confined to the natural world of cause and effect." For the law is not principally concerned with establishing what is and has been, nor in predicting what will be, but rather with the use of these in deciding what *should* be. Following the example of the law, Dr. Board himself steps outside the natural world of cause and effect and there finds that what is "worthy" of society is correction rather than condemnation and punishment.

This is a suggestion for which we should thank him if he recognized it as a suggestion. As the "operational meaning or 'cash value' of the concept (of criminal responsibility)" we are more likely to find ourselves somewhat suspiciously counting our change. For example, Dr. Board's operational analysis of criminal procedure reveals to him the workings of protective, corrective and humane principles, and something else which he calls "vengeance to the criminal." Although this last is apparently to be found in the operation of the law, it is not therefore, as you might expect, a part of its operational meaning. It is a "contaminant." This strange qualification of an operational concept (in which the metaphysician will recognize the old "accidental attribute") is required because the investigator finds such aims "rejected as unworthy of society,"—rejected, evidently by Dr. Board, since they are retained as contaminants by society. Such an operational analysis, which includes the import of some operations and excludes the significance of others, resembles not so much operational philosophy as it does operative surgery. Post-operatively a contaminant is

¹ V.A. Hospital, West Haven, Conn.

all that remains to the criminal law of the concept of Justice which afforded it such satisfaction in better days. If we agree to this we must be convinced that talk of retribution and debts to society is a rare and uncharacteristic way of referring to criminal responsibility.

Radical surgery, of course, has its indications and Dr. Board is obviously more interested in finding a workable meaning of criminal responsibility than elucidating the common meaning. Accordingly he states that "while these [his own] value judgments may have metaphysical origins, carrying them out requires scientific rather than metaphysical conceptions." If there is no way of applying common concepts, they must be excised. But is there not a sense in which the law can be considered an operational definition of moral responsibility? The problem of workability only arises with recent attempts to make exceptions to what has in criminal law been an obviously retributive system (and which remained so long after it recognized insanity). It is a discomforting thought that the problem of how to be more discriminating in applying the concept of moral responsibility is here solved by eliminating the entire concept. One can almost sympathize with those who learn from this not to discriminate.

We have here one further example of the failure (well illustrated in modern philosophy) to distinguish between explication and legislation. Explication is the replacement of a vague and shadowy notion with a clearly defined concept that comes as close to it as a clear concept can come to a vague one. If that vague notion is sufficiently obscure and its import distasteful to the explicator, he will be overwhelmingly tempted, while concealed in the dark, tortuous alleys of confused meaning, to secretly assassinate the offending concept and sponsor forth some favorite imposter in its stead. Legislation is so much simpler than explication and can look so like it. But perhaps of all philosophers, it is the operationalist who should have the greatest patience with the vaguenesses of the law, for this at least is already a set of operational definitions and having anticipated, so to speak, the greatest part of the

analysis, may be permitted its gaucheries and inconsistencies; if it had none the operational philosopher would have no job. Part of this job is to determine by the uses of the law, why certain wrongs are exempt from the need for retribution. To say that all are exempt, as Dr. Board does, is to abandon explication for legislation.

II

But if, as philosopher, Dr. Board should have seen how intrinsic the notion of retribution is to the criminal law, as a psychiatrist he would be expected to recognize how retributive is the punishment demanded by the conscience of the people whose law, after all, it is.

When Dr. Board asks "Where in the range of psychodynamics does moral responsibility suddenly or gradually appear?," his rhetorical question exposes itself to an answer. To be sure, and this is his main contention, nowhere do condemnation or moral directives appear as statements of psychology, but they do certainly appear in statements of psychology, and it is in psychology that these moral directives first receive their meaning(2). This being so, the psychiatrist is in the very best position to appreciate those retributive, punitive requirements of the mentality that creates the law. To nevertheless ignore them in the created law is as much a disservice and as ultimately futile as to pretend that people's consciences can serve solely as a guide to better behavior and never as a source of remorse or indignation.

But not only will the wise psychiatrist thus confirm what the careful philosopher finds in his analysis of criminal law; he will have the additional advantage of anticipating the confusion and contradiction seen in its application. He duly points out the ambivalence and complexity of what his patients consider to be fairly simple attitudes. He should not be the last to recognize that an institution like the law is used to implement many social aims, any two of which would be entirely consistent and compatible only by the most extraordinary accident. As a psychiatrist it better not try to instruct the public in these divergences than to conceal them behind a false rationalization. The apparatus

of the law is used for marriage counseling, child-rearing, psychiatric steering, social change. It is also used to avenge injustice. Depending on the temper of the times some of these aims may eclipse others. Eclipsed aims however vanish no more readily than repressed ideas, and will not be exorcised by labeling them contaminants. To say that "punishment as a method of rehabilitation is given in the same educative spirit as in punishing a child" is to say that punishment is only rarely a method of rehabilitation. Witness the remarks of the magistrates who dispense the greatest quantity of justice in our culture.

The lesson to be learned from Dr. Board's interesting attempt to rationalize the law by heeding only its protective and corrective aims is that the search for the compound of conflicting interests served by the law cannot be impatiently replaced by a simpler reconstruction. Such a reconstruction is irrelevant to the need the law fills, which is to bring society's complicated aims to just that kind of expression demanded by their relative weights. Opinions based on an autistic law created by the expert will be properly held, in the apt words of Dr. Board's quoted opponent, not "responsive to the question the jury must answer."

The only fruitful method is to continue the difficult and frustrating attempt to follow out all the hints that the exercise of the law provides. If there is a difference between society's attitude to the child, where punishment is educative, and its attitude to the adult criminal, this is operational evidence that culpability in the law has some relation to psychological development, and it provides operational hints as to what qualifies moral guilt in the mentally ill criminal. Does an ego require a certain integration before guilt seems appropriately applied to it? In punishing are we interested in counterbalancing an action reflecting a wrong sense of values, and do we therefore require a minimum of apprehension of facts or reality testing in order to insure that the distortion is really one of values? Are we perhaps offended by only

certain kinds of wrong value pictures? Whatever the answers, we will not discard them for inconsistency, since we know beforehand that under certain circumstances we will exercise sympathy where we might indignation, and that people will sometimes be more concerned about therapy than justice.

SUMMARY AND CONCLUSIONS

Dr. Board's objectives can only tend toward a happier society. His failure to distinguish between suggestion and analysis prejudices his worthwhile objectives in the following ways:

1. It leaves him unarmed against the resistances of society which go unrecognized.

2. It compromises the effect of the psychiatrist's most potent weapons,—expert advice and education, by concealing them in a tendentious special plea for the values of the psychiatrist.

3. In the manner of so many current political positions, it blurs the meaning of society's conflicting values by insisting that they are perfectly realized in the tissue of compromises and violations that alone can give them expression.

4. Finally, one suspects that there will come a time when the psychiatrist, accustomed to the stationary ethical foundation he has artfully built and unprepared for the heaving sea of felt principles, will feel in himself the upsurge of the rejected "contaminant" and be overcome by a moral malaise without remedy.

REPLY TO DR. FRIEDMAN

RICHARD G. BOARD, M.D.

In my article, "An Operational Conception of Criminal Responsibility," I tried to be as specific and precise as I could so that any inconsistencies in logical development would be easy to spot. Dr. Friedman believes that he discerns such mistakes. I hope that my objections to his objections will reassure him that I am not unfamiliar with the issues he has raised.

To begin with, Dr. Friedman points out that I did not document my assertion that the concept of moral responsibility was a metaphysical rather than scientific idea. I didn't think it was necessary to prove it for several reasons. First, what moral responsibility is, or is not, was not a central issue in my article which was concerned with setting forth an alternative to that vague idea. Second, while the subject may still be disputed by system philosophers, I believe that it is no longer taken seriously in science. For example, in one of the very articles cited by Dr. Friedman, Dr. Robert Knight makes it abundantly clear that any concept involving free choice has no place in scientific theory.

Dr. Friedman's next objections result from his failure to differentiate between criminal law as a system of proscriptions about behavior and the procedure of applying this system in the courtroom. For he quotes me as saying "the law constitutes an operation exclusively confined to the natural world of cause and effect" whereas the statement was: "the administration of the law constitutes etc." However Moses got his commandments, he had to descend the mountain to administer them in the valleys of cause and effect. Replacing a metaphysical ritual in administering criminal law by a deterministic, scientific procedure does not involve throwing away the value judgments such as justice blueprinted in the laws to be administered.

In the midst of this confusion, Dr. Friedman introduces a quotation from Freud in order to show that moral responsibility has something to do with cause and effect. Please note that Freud uses the term responsible rather than morally responsible. What does responsible mean in this context? To clarify

this, let me translate the quotation into more precise language: "Obviously, a constellation of forces within the individual results in the 'evil' impulses in his dreams. What other forces can cause them? Unless the content of the dream . . . is inspired by alien spirits, the location of these forces causing the dream is within the dreaming individual." Perhaps also implied is this: "And so it is to this individual and these forces that we apply the forces of therapy." Now certainly this statement is naturalistic enough. With but slight modifications it could apply to almost any animate or inanimate event. In this sense, a landslide is responsible for obstructing traffic and a murderer is responsible for his victim's death. "Responsibility" is used as a way of referring to cause and effect linkage and to locate the forces involved within a certain individual. And it means no more. But this is not the moral responsibility of the courtroom nor the criminal responsibility founded on that concept. If it were, how could we find even the sickest dreamer "irresponsible." If this kind of courtroom responsibility indicates causal linkage between actions and the personality, who could ever be judged irresponsible? What causes the "freakish, spontaneous act totally unrelated to the personality"—an alien spirit? As scientists we would do well to drop the whole idea of responsibility. It isn't needed to get things done with everything in the universe except human behavior and it isn't needed to get things done with human behavior. In my article the quantitative operational concepts of deterrent efficiency and efficient punishability replace the confusing idea of criminal responsibility.

Dr. Friedman's concern that I may have introduced some value judgments of my own in pronouncing retributions or vengeance an unworthy contaminant in the judicial process seems to stem primarily from his failure to appreciate that there are 3 general levels involved in criminal law. First, there is the blueprint for behavior, the laws themselves. Second, there is the blueprint of how to administer the laws. Third, there is the administration of the law by the all too human

judge and jury. My paper concerned the second level, the blueprint of how to administer the law, explicating the current value systems involved and the logic of their application to the natural world of criminal behavior. Regarding the value judgments inherent in the blueprint for administration, my point was that they have gravitated away from retribution and toward correction. Such things as public hangings, floggings, cruelty toward the imprisoned and other food for vengeance are discouraged these days because of this change in values regarding the administration of the law. Retribution and vengeance toward the criminal still flourish, as Dr. Friedman points out, but only at the third level, the all too human performance in the courtroom. But they are continually hedged in and circumscribed by the blueprint of administration. I say all too human because the law and the blueprint for its administration seek to be better than any man—more impartial, less vengeful, etc. This is one reason we prefer a government of law rather than men and regulate the administration of law rather than trusting too much to the emotional vagaries of judge and jury. In regard to the trend in values characteristic of the blueprint for administering the law, the emotions of judge and jury, vengeful or otherwise, stand as contaminants in the judicial process of government by law. In view of the progress already achieved in circumscribing these contaminants, Dr. Friedman need not be too pessimistic about further improvements.

Next comes Dr. Friedman's assertion that I was too selective in my operational analysis of criminal procedure in conspicuously omitting vengeance toward the criminal. I have already indicated why this portion turns out to be a contaminant in regard to enlightened administrative blueprints. But Dr. Friedman's conception of operational analysis intrigues me. Unfortunately, there has been a trend toward broadening the concept of operational analysis since Bridgman first formulated it until it can cover almost anything. Thus it is becoming a favorite of philosophers. It is possible that Dr. Fried-

man, in his role of careful philosopher, has achieved the *reductio ad absurdum* for this trend. As I get it, he seems to feel that any vague idea can be operationally analysed—even the magical rituals of the primitive, I would suppose. But there are concepts that are operationally meaningless and in such cases there is no alternative but to legislate rather than explicate. I regard moral responsibility as just such a concept. The fact that an elaborate courtroom ritual exists whereby it is supposedly applied confers no more operational validity upon it than conceiving of golden mountains will make one rich. As I indicated explicitly in my article, I set out to redefine criminal responsibility and made no bones about the fact that I was not intending an operational analysis of moral responsibility. I don't think any is possible. Dr. Friedman need not fear that the concept of moral responsibility will be assassinated in "the dark, tortuous alleys of confused meaning." That is where it thrives.

Regarding correction *vs.* retribution as an aim of the law itself, I am reminded of Professor Stace's observations on the subject. The impositionist theory, personified by Moses obtaining the law from God, holds that laws are imposed on mankind from without. The immanent theory holds that laws are evolved by mankind. Science has tended to confirm the latter. The law is viewed as an institution evolved by societies to maintain themselves. As adaptive mechanisms the laws and even the idea of retribution are corrective mechanisms maintaining society. Like many corrective mechanisms, retributive law is as inefficient in the long run as a neurotic symptom.

Having been jumped so frequently between the roles of philosopher and psychiatrist in Dr. Friedman's paper, I would seek final asylum in his role of wise psychiatrist. He had some nice things to say about my article before the inevitable, "however," and this suggests to me that our agreement may be more extensive than our differences. In turn, I have had to be abrupt and unconstructive. I hope that both of our discussions will stimulate further study of my article.

SOME PSYCHIATRIC NOTES ON THE *ANDREA DORIA* DISASTER

PAUL FRIEDMAN, M.D.,¹ AND LOUIS LINN, M.D.²

On July 25, 1956, at 11:05 p.m., the Swedish liner *Stockholm* smashed into the starboard side of the Italian liner *Andrea Doria* a few miles off Nantucket Island, causing one of the worst disasters in maritime history. The authors were passengers on the Europe-bound *Ile de France* and spent approximately twelve hours, independently, interviewing and observing the survivors, the crew of the *Ile de France* who participated in the rescue operation, and the passengers aboard the *Ile de France*. It must be noted that the cause of the disaster was purely a matter of speculation at the time and there was no factual basis for establishing culpability for it. Subsequent inquiries succeeded in establishing the circumstances of the accident, and the authors are gratified that their observations can now be measured in terms of confirmed facts and thus assume more realistic value. For, as psychiatrists and psychoanalysts who happened to be on the spot, we were in a unique position to make immediate observations. Our data, carefully recorded after interviews with a large number of people, do not constitute a systematically scientific study of the experience, but may represent a modest contribution to the psychology of disasters.

THE STATE OF INITIAL PSYCHIC SHOCK

The emotional state of the survivors may be divided into two distinct phases: the state of initial psychic shock and the recovery phase. During the phase of initial shock the survivors acted as if they had been sedated. It is noteworthy that but a minimal quantity of sedative medication had to be administered during this time. Thus, it was as though nature provided a sedation mechanism which went into operation automatically in most cases. The survivors presented themselves for the most part as an amorphous

mass of people tending to act passively and compliantly. They displayed psychomotor retardation, flattening of affect, somnolence and, in some instances, amnesia for data of personal identification. They were nonchalant and easily suggestible.

Comment.—The attitude of helplessness and dependency identifies this condition as a state of emotional regression in which people who are normally capable of functioning on an emotionally mature, adult level become childlike in their feelings of personal inadequacy and in their tendency to overestimate the powers of those offering help and leadership. In their state of shock, the survivors of the *Andrea Doria* could be compared to the survivors of the concentration camps who were found to have developed a state of affective anesthesia as a defense against the dangers and anxieties to which they were continuously exposed (7, 8). As early as 1918, the same reaction pattern was observed by Jones (9) as well as by Ferenczi, Abraham and Simmel (2) in victims of war shock; and when Freud (5) spoke of a "protective barrier against stimuli" (*Reizschutz*) he actually defined a mechanism which is probably mediated by the ascending, activating reticular system which protects the central nervous system when exposed to stimuli of excessive intensity. Because of this protective mechanism the survivors of the *Andrea Doria*, at first, could not be approached or induced to talk.

THE PHASE OF RECOVERY

After their initial shock had worn off, it became possible to question the survivors. As a matter of fact it was usually unnecessary to ask questions, since so many of them had a great need to tell their story. And they did tell their story over and over again, to anyone who would lend a willing ear. Characteristically, they showed pressure of speech and an apparently compulsive need to tell the story again and again, with identical detail and emphasis.

¹ Associate Attending in Neuropsychiatry, Beth Israel Hospital, New York City.

² Associate Attending Psychiatrist, Mount Sinai Hospital, New York City.

Comment.—We were impressed with the similarity between these repetitive narratives and the repetitive dreams of the traumatic neurosis. Each represents a psychological reliving of the trauma, as part of an attempt to master an experience that had proved overwhelming.

PREJUDICES AND PARANOID ATTITUDES

We were struck by the frequency with which the survivors who spoke to us were angered. They expressed certainty that the accident was the fault of the *Andrea Doria*, even though the details of the catastrophe—such as the extent of the survivors' misery, the irreparable loss of the beautiful ship, the relatively intact state of the *Stockholm*—favored sympathy on behalf of the *Andrea Doria*. This prejudice was based on the *a priori* acceptance that Swedes are dependable, faultless sailors and people of impeccable integrity and reliability, while Italians on the other hand are childlike and irresponsible, tending to pursue their pleasures instead of their duties.

Comment.—It is interesting to remember at this point that during hearings investigating the causes of the *Titanic* disaster in 1912, the term "Italian" was freely used as a synonym for "coward." "There were various men passengers," declared Steward Crowe of the *Titanic* at the U.S. inquiry, "probably Italians, or some other foreign nationality other than English or American, who attempted to rush the boats." This contention, proven false, formed the basis for a successful libel suit against this officer. It is also somewhat ironic to recall that in his book on the *Titanic* disaster, *A Night to Remember*, published less than a year before the *Andrea Doria* catastrophe, Walter Lord (11) expressed the view that some of the prejudices of the age went down with the *Titanic*, notably the belief in the superiority of Anglo-Saxon courage. Such a notion was proved overoptimistic by opinions voiced aboard the *Ile de France*. The absolute necessity for finding a scapegoat, for locating somebody who was at fault, found an outlet once again in the paranoid projection of prejudice on the part of people on the *Ile de France*; not only demonstrating that stereotype thinking

is still prevalent, but dramatizing its capacity to dominate opinion during periods of crisis and its influence in distorting perception and judgment.

Such attitudes are familiar expressions of the quest for a scapegoat, a psychological device for turning aggression outward. It is part of the overall attempt to master an overwhelming trauma. The survivors' tendency to blame the *Andrea Doria* for their misery derived from their feeling of having been failed. They suffered a narcissistic injury which may be compared to the feelings of a child who finds that the strength of his father has turned out to be a fallacy. Let us not forget that the *Andrea Doria* had been considered unsinkable, which conveyed a great sense of security in her passengers; yet there they were having to abandon her and being abandoned by her, experiencing the inability of a parent to cope with disaster.

The facts are that the crew of the *Andrea Doria*, with the expected exceptions, acted with generosity and even heroism. It has been recorded by Cornelius Ryan (13) in an article for *Collier's* and by Walter Lord (12) in an article for *Life* how an Italian cabin-class waiter and several Italian crew members cooperated in trying to free the wife of a passenger from beneath a collapsed partition, spending five hours in the futile effort. Many other instances of helpfulness and altruism on the part of crew members are on record, leaving no basis for condemnation.

Expressions of prejudice were not confined to fixing the blame for the accident on the *Andrea Doria*, but also manifested themselves in the contempt voiced by some passengers on the *Ile de France* toward Italian immigrant survivors because of their uncontrolled demonstrations of despair. To some who expressed these feelings it was explained that patterns of emotional expression are culturally determined and that they vary, in a given national group, from one economic stratum to another. It was also indicated to them that the control of emotional expression under stress is not a reliable measure of courage and strength of character; furthermore, that from a psychiatric point of view the expression of one's true feelings, particularly during bereavement,

serves a useful adaptive function in the mental health of the individual.

Such opinions among *Ile de France* passengers thus were clearly based on paranoid projections of stereotyped prejudice, in contrast to the reactions of the rescued whose resentment toward the *Andrea Doria* stemmed from the violent destruction of their sense of security and dependence.

THE PROBLEM OF COMMUNICATIONS

The most frequently voiced charges were: that no announcement had been made about the nature and gravity of the accident, and that no concerted rescue effort was made.

Comment.—These have been answered by the fact that the first impact of the collision caused a power failure on the *Andrea Doria*, putting the public address system out of commission. Moreover, the ship rapidly developed a severe list which, coupled with oil slicks on the decks, made it imperative for each person to save himself from sliding into the sea. These circumstances also made it almost impossible to circulate information on foot. As a matter of fact, Italian crew members did make their way about on the sharply inclined decks, urging passengers to remain calm, and there was indeed very little panic.

LEADERSHIP

The foregoing facts compel a consideration of the problem of leadership in crises. Because of the conditions on the *Andrea Doria* just described, groups of people were largely immobilized and isolated; this created a necessity for each group to evolve its own leader. In several instances, priests and nuns stepped into the breach. By virtue of their training they were prepared to do so, just as the predominantly Italian Catholic immigrant group was prepared by training to accept their leadership. Primarily they participated in the practical problems of the rescue operation, only secondarily providing religious solace to those who asked for it. In other groups there were individuals not otherwise identifiable who likewise assumed leadership voluntarily.

Comment.—The willingness of some people to assume leadership of a group in dis-

aster situations has repeatedly been observed, and a systematic study of such individuals might help us to identify the qualities that make for leadership, enabling us to concentrate our civil disaster training on such persons. The existence of a corps of trained people endowed with qualities of leadership may make the difference between success and disaster in community emergencies. A leader who understands the psychological importance of identifying with a group, as a device for combatting feelings of individual helplessness and despair, will make use of techniques which promote positive group action. Not only is effective leadership the most important weapon in combatting mass hysteria, but, as stated by Sperling (14), mass hysteria as such can be defined as a failure of leadership. Whether a group reacts to a crisis with self-control and cooperation or with egotism and chaos depends almost entirely upon the quality of leadership, and the vital importance of developing able leaders is well illuminated by Freud's (6) statement in the *New Introductory Lectures on Psychoanalysis*: "A psychological group is a collection of individuals who have introduced the same person into their super-ego, and on the basis of common factor have identified themselves with one another in their ego."

CHILDREN IN DISASTERS

The application of the "women and children first" principle on the *Andrea Doria* resulted in some poignant and, in at least one case, tragic separations and isolations. It can be said that this principle, which prevails in our culture during catastrophes, frequently results in the isolation of children from their parents with possibly disastrous psychological consequences.

Comment.—This view finds ample support in the Freud-Burlingham (4) reports on *War and Children*. During the bombings of London in World War II it was repeatedly observed that children exposed to extremely violent bombing scenes, even those partly buried by debris, showed no particular signs of having been affected if they were in the care of a parent during such incidents. Bombed-out children would arrive at a shelter, in the middle of the night, showing no

undue disturbance when accompanied by parents or by familiar parent substitutes. Serious psychological disturbances were confined largely to children separated from their parents during such experiences. It was the main conclusion of the Freud-Burlingham reports that such disasters as war have comparatively little significance for children so long as they only threaten their lives or material comforts, but become enormously important the moment they break up family life and uproot the first emotional attachments of the child within the family group.

In another study of emotional reaction of children to disaster, Bloch, Silber and Perry (1) clearly established a post-disaster increase in dependency needs characterized by symptoms of regressive behavior. They observed that a greater need for belonging and a reaching out for others were typical disaster responses in children, but that such manifestations would tend to be arrested or at least alleviated by the presence of a parent during disaster situations.

These principles found a practical application during the Arab-Israeli war of 1948 when the Israelis adopted the practice of requiring one parent to remain with the children if the other were assigned to a hazardous mission, so as to minimize the likelihood of children becoming doubly orphaned. The authors are convinced that a modification of the "women and children first" rule by insistence that a parent accompany the child, even if the only parent available be the father, would represent a sound application of modern psychiatric insights.

OFFICIAL IDENTIFICATION LISTS

The lack of an official list of survivors contributed to the delay in the reunion of families separated during the disaster. As far as we could ascertain, such a list was not initiated with the rescued during their stay aboard the *Ile de France*; this and similar delays on other vessels and at collection centers may account for the fact that several days passed, in some instances, before families were reunited.

Comment.—Prompt establishment and publication of such identification lists is an important leadership device in combatting

panic and maintaining morale. This device serves a twofold purpose. First, it is reassuring to the bewildered survivor to be recognized as an individual, the mere recording of his name, address and next of kin helps to re-establish, in his mind, the intactness of his shattered ego. The instances of amnesia during the initial psychic shock phase, to which we referred above, tend to support this concept. Secondly, to expedite the reconstitution of broken family units is a matter of equal psychiatric importance for the isolated individual. A considerable number of passengers on the *Andrea Doria* were immigrants coming to the United States, for whom the catastrophe represented a complete loss of identity in both the physical and the psychological sense. For members of this group, the loss of their passports constituted the end of their individuality; in contrast to the tourists, for whom the loss of passports was merely a transitory predicament which failed to damage their identity: they could always return to their background, their money and their roots. But for the immigrant the passport symbolized not only his individual identity, but also his sense of belonging, and it is not surprising that to save it was of greater importance to him than the saving of physical property. Those who could save their passports managed to maintain their pride, even if they had lost all their material belongings; those who failed to save them became "stateless persons," temporarily at any rate, whose whole sense of belonging went down with the *Andrea Doria*. The publication of an identification list of survivors would have brought a great measure of relief to these people for whom the loss of a passport also meant a discontinuation of their body image, a psychic loss which would have been relieved by being included on such a list.

REACTIONS AMONG THE ILE DE FRANCE PASSENGERS

Many lay persons, in subsequent discussions of the *Andrea Doria* disaster, have remarked: "How depressing it must have been! It must have cast a pall over the rest of your trip." This attitude, which implies a deep identification with the victims, can be

summarily dismissed. To our knowledge, there were only a few passengers who became so depressed that they decided to interrupt their trip to Europe and return home when the *Ile de France* docked at New York. It was not difficult to ascertain that these people had been depressed prior to their departure and that their depression was merely reactivated by the events at sea. In general the impact of the catastrophe did not have as disruptive an influence as one might think.

Comment.—It must be remembered that most of the passengers on the *Ile de France* were asleep at the time of the collision. They were stupefied when, upon awakening, they found out what had taken place, and manifested rather a feeling of shame and of having been cheated of the experience. One of the authors vividly recalls his feelings of anger at not having been awakened and of deep disappointment when his services were not needed. The passengers somehow reminded one of soldiers during a war who have remained behind the front lines and never got to see a real battle. This usually generates a sense of guilt, which no doubt was also present in all the passengers who showed a readiness to help as much as they could and even displayed acts of generosity.

All this points to a confirmation of the principle that guilt can be a positive force of social good when given proper channels of expression in terms of morality and social approval; in the process, personal neurotic anxiety and depression may be relieved.

PERCEPTUAL DISTORTION

Several passengers on the *Ile de France* were awakened by the sound of lifeboats being lowered to pick up the *Andrea Doria* survivors and went back to sleep with the thought, "this is only a drill and is of no concern to me." One man expressed this aloud to his wife and got up, reluctantly, only at her insistence that drills do not take place at 2 a.m. A particularly fascinating experience was reported by a man who heard voices outside his cabin. He got up and saw several lifeboats in the water. The people in them wore the conspicuous orange-red life preservers, and in the brilliant spotlights of the ship these colored life preservers had, to

his mind, a festive quality. The sounds outside, which were actually expressions of misery, sounded to him like laughter and gaiety. It seemed, to quote him, "like a carnival in Venice." He went back to bed muttering to himself that this was carrying the Frenchman's love of fun a little too far and that one should not cavort so noisily in the middle of the night. He was just falling asleep when the true significance of what he had seen hit him, and he leaped from his bed and got dressed. Several others reported hearing sounds outside the portholes which they interpreted as sounds of festivities and merriment.

Comment.—In each of these cases we find perceptual distortions which parallel those taking place in sleep. Stimuli received during sleep are transformed into dreams that encourage the continuance of sleep. In our examples the subjects were already awake, but interpreted their sensory impressions in such a way as to justify a return to sleep; i.e., in a way designed to relieve anxiety which would disturb sleep. Instances of sensory distortions under similar disaster circumstances are described in Lord's (11) book on the *Titanic*:

Individual voices were lost in a steady, overwhelming clamor. To Fireman George Kemish, tugging at his oar in Boat 9, it sounded like a hundred thousand fans at a British football cup final. To Jack Thayer, lying on the keel of Boat B, it seemed like the high-pitched hum of locusts on a midsummer night in the woods back home in Pennsylvania.

PROPERTY

During the evacuation of the *Andrea Doria*, most passengers were forced to abandon their belongings. Such exigencies throw an illuminating light upon feelings toward property in disasters. What do people try to save under these circumstances? What do they choose to take with them in the process of trying to save their lives?

The main concern of the immigrant group was focused on the effort to save their passports, disregarding articles of material value. For members of this group, as we have noted, a saved passport meant the continuation of body image, the tangible affirmation of survival, the maintenance of their sense of belonging and pride. But of course, too,

the saving of valuables appeared to be secondary. In some instances, women already enjoying the safety of a lifeboat would drop their jewelry into the ocean.

Comment.—One might speculate about the sacrificial symbolism of such acts which imply the offering of sacrifice as an expression of gratitude for the sparing of life. The fact that a lady who had saved her mink stole became the object of ridicule would seem clearly related to such feelings. While behavior observed during the sinking of the *Titanic*, like our notes on the *Andrea Doria* catastrophe, revealed a rich variety of attitudes toward property, the former would equally tend to confirm the existence of a need to offer material sacrifice in exchange for life. The following examples are taken from records of the *Titanic* affair. One person took with her a musical toy pig, another a bible, another a revolver and a compass, another only books, another four oranges. Two outstanding instances were noted in Lord's book, both expressing a curious disregard for valuable belongings: one was the case of Mrs. Dickinson Bishop who, having left behind 11,000 dollars' worth of jewelry, sent her husband back to the cabin for her muff, the other, the famous decision of Major Arthur Peuchen to abandon 300,000 dollars in stocks and bonds and to take merely a good-luck pin and three oranges. Although there were others, like Mrs. Adolf Dyker, whose main concern was the saving of their jewelry, the outstanding feature of property rescue was the secondary importance attached to articles of monetary value. The authors found a striking parallel, in these reports, to incidents observed in the more recent disaster.

CLOTHING

In the course of leaving the *Andrea Doria*, most passengers had to shed their shoes and partially also their clothes. Thus they came aboard the *Ile de France* shoeless and, many of them, scantily clad. Crew and passengers of the rescue ship were generous in their contribution of clothing articles; yet it caught our attention that some of the survivors, mainly among the younger people, were not too eager to accept the garments

thus offered to them. But their attitude was in sharp contrast with that of the majority who felt deeply ashamed of being unprotected, when given of this opportunity their means of becoming dignified human beings again.

Comment.—These people looked upon clothing—as Flügel(3) observed in his brilliant exploration into the psychology of clothes—as protection against the unfriendliness, the enmity of the world as a whole, and as reassurance against the absence of love and security. Being in unfriendly surroundings—and to these people, who had to abandon the familiarity of their own ship, the chilly decks of the *Ile de France* must have appeared unfriendly—their natural tendency was to button up, to wrap garments around their bodies. They felt agreeably strengthened and supported by clothes in such circumstances.

It was interesting, therefore, to speculate on the motivations of those younger people who hesitated to accept the offers of clothing. One might ascribe to them, on the one hand, a feeling of bravado and assumed poses of heroism, possibly tending to exploit their situation in the hope of obtaining greater, more substantial rewards upon their arrival in New York, in the manner of a child who rejects a small toy while waiting for a bigger one. On the other hand, and perhaps more significantly, one might conjecture that they were also gratifying exhibitionistic fantasies; i.e., that they derived a narcissistic pleasure from the display of their bodies and that their lack of eagerness to accept clothes indicated a hesitation to sublimate it.

The behavior of both groups with regard to clothes, as well as the contrast between the two attitudes, provides a striking dramatization of Flügel's findings that articles of clothing are essentially in the nature of a compromise between conflicting elements for the establishment of harmony, in the same way as neurotic symptoms represent a compromise between conflicting and largely unconscious impulses.

SUMMARY AND CONCLUSIONS

We have presented observations concerning the phases of initial psychic shock and of recovery; prejudices and paranoid attitudes;

the problems of communications, of leadership and of children in disasters; the role of official identification lists; reactions among the *Ile de France* passengers; instances of perceptual distortion experienced by the latter; and various attitudes of the survivors toward personal property and toward clothing.

It is our hope that these observations will be of interest and possible value to those concerned with the psychological problems of civil disasters. The sinking of the *Titanic* in 1912 prompted major reforms and improvements in the physical aspects of safe navigation. Our psychological exploration of the *Andrea Doria* disaster, unsystematic though it be, points to avenues of further study into the following areas:

(a) Our notes on the role of prejudice in the development and resolution of crisis might merit the attention of the World Federation for Mental Health in its program for the prevention of social and individual emotional disorder through the systematic search for tension-reducing techniques. Our observations also emphasize the importance of paranoid reactions which are apt to arise in crises and to intensify conditions of chaos.

(b) The *Andrea Doria* experience points up the fallacy that all disaster training must be based on the expectation of nuclear warfare. Men of leadership caliber who shy away from preparations for atomic attack might participate more wholeheartedly in programs which emphasize training for such peacetime disasters as may befall anyone.

(c) The introduction of leadership devices that are based on established psychological needs. In our discussion of the "women and children first" principle we pointed out the desirability of having at least one parent accompany the child. The need for such practice has been amply demonstrated during previous crises in recent his-

tory. The importance of a speedy method of collecting and publishing survivor identification lists in disasters has also been established as a major device designed to aid survivors in maintaining their identity and to alleviate the traumatic content of their experiences.

The authors do not attempt to draw any general conclusions on human nature from the *Andrea Doria catastrophe*. But they do believe that the introduction of modern psychiatric principles in these areas will effect progress in important aspects of human welfare.

GROUP PSYCHOTHERAPY: INDIVIDUAL AND CULTURAL DYNAMICS IN A GROUP PROCESS

MARVIN K. OPLER, PH.D.¹

Group psychotherapy depends on the dynamics of three processes. These processes are interwoven. Simultaneously, they involve the group, the individual and his cultural background. To date, there has been relatively little attention paid to this interweaving of three basic elements, their relative weight or effects, and the influence of one upon another during treatment. Since group techniques are used constantly and increasingly in hospitals and in private practice, a systematic approach to the total process is required.

This account discusses relevant aspects of the total process in which each term, the group, the initiator of therapy (the psychiatrist), treated individuals, and a variety of cultural backgrounds all play a role. For purposes of analysis, these relevant aspects of the listing just given must be determined. We therefore discuss them in the order of (a) the group, (b) the individuals and (c) cultural backgrounds represented by the physician and the treated individuals. In so doing, we shall deal with affective constants and variables associated with the terms listed as if they represented a continuum ranging from more optimal emotional conditions to those involving greater disturbance. We therefore begin with the group.

While most group psychotherapy involves Freudian presuppositions, Freudian notions of a necessary procedure are often lost in the complexity of the group process. We shall regard Freud's voluminous writings on psychotherapeutic procedures as being in "the public domain" and shall purposely avoid a list of specific references. However, such various works as Freud's *Interpretation of Dreams* or his *Constructions in Analysis* readily come to mind as instances of the assertion that therapeutic interpretations are really reconstructions of the past. In *Constructions in Analysis*, for example,

it is stated clearly that only further steps in the analytic procedure enable the therapist to decide upon "correctness or uselessness" of such constructions. This operational procedure in psychoanalysis, which Freud stated was conjectural, awaiting "examination, confirmation, or rejection" really accords well with the operational and exploratory character of most group sessions. However, Freud paid little attention to concomitant group influences in treatment sessions. Even in the *Psychopathology of Everyday Life*, the impression one has is that two-person situations, rarely with a modest audience of onlookers, predominated. Many of these instances involved the individual and his errors of omission or commission, acting alone.

What, then, does the group—even a somewhat amorphous and experimental one—add to this picture? The last decade has seen great development of research interest in the organization and functioning of small groups. Hare, Borgatta and Bales have assembled much of this literature(5). From mountains of research, the flowers of information are rare, but they have definite uses, when catalogued, for group psychotherapy. In 1940, the anthropologist, Chapple, discovered all persons have characteristic or normative rates of communication, described as interaction levels. Experimentally, the rates showed modification by interaction constants of others in the same situation. For example, as politeness or shyness in strangers wore off as a function of time spent together, each approached their already noted, or normative, levels(3).

Psychiatrists add to this a crucial observation, namely that a mental illness may drastically modify such normative interaction levels of personal communication still further. Again to cite theoretical statements of this idea, already in the public domain, one could note that this particular observation formed a large part of Sullivan's *Interpersonal Theory of Psychiatry* or of Fromm-Reichman's *Principles of Intensive Psy-*

¹ Vis. professor of anthropology (social psychiatry), department of psychiatry, Cornell University Medical College, New York City.

chotherapy. Stanton and Schwartz's *The Mental Hospital* is a third well-known work replete with such instances. What is arresting about these three well-known works, taken together, is that they stress almost with increasing emphasis that the interpersonal theory of illness, or the interpretation of schizophrenia given by Fromm-Reichman, or the responses of patients to milieu reported by Stanton and Schwartz record the levels of personal communication as functions of both longstanding illness processes and more contemporaneous experiences. Although the parallel literature from group psychotherapy is too extensive and scattered to adduce here, group psychotherapists know that a particular "emotional climate" or discussion-sequence may modify individual and group interaction rates noticeably.

In the field of small group research, rate is the *quantity* or *amount* of human, symbolic interaction. We already know this quantity, as a total, is increased in the group process. However, besides the quantity or amount, there is the further question of the quality or depth of expression. In the three volumes mentioned, it is stated both theoretically and concretely that *quality* or *depth* of expressive communications may range from superficial to highly expressive symbolizations of subjective states. Small group research has often not troubled to make such distinctions as to content. Yet, in psychiatry, the quality or depth of the content of communications has been of overwhelming importance as soon as psychodynamics became a central focus of therapeutic procedures.

However, while amount or depth of communications has each been noted in psychotherapy, a third element seems to be involved if we are to deal with affective constants and variables associated with the terms we have listed. Both small group research, and considerations of the depth of expression, may easily overlook this third aspect. While the Freudian system suggests expressions in depth may be cathartic, increasing emphasis on ego structure has warned against an unbridled flooding of impulses. Much of this discussion has been couched in terms of transference and countertransference as if larger group relationships hardly existed.

The author, therefore, introduces as the third term the *emotional valence*, or *combining power* of an affective state, and of its verbal and non-verbal symbolizations. Here one thinks not simply of depth of emotion, but of characteristic style of affect. Polar examples might be hostile or cooperative utterances. But in reality, human behavior is so modified by symbolic constructs resident in cultures and in subcultures that no individual exposed to cultural backgrounds at all fails to incorporate emotional valences towards persons, objects and ideas. These are best called human *and* cultural values. Obviously, they relate to the social role expectancies and functioning of persons in a static or in a changing cultural scene. Equally, the social roles and statuses are themselves dynamic and multiple since they apply throughout the life-cycle.

To illustrate, in a scale, one who has participated in group sessions can discern the illness polarity in low rates of interaction as to quantity, depth or emotional valence. Actually, these aspects interblend or interpenetrate, affecting one another. For example, low rates of interaction may be mixed, or modified by, hostile non-verbal communications. As is known from studies of schizophrenics, the rate of interaction should not be confused with lack of reaction. Blocking, rigidity and withdrawal may all be defenses changing interaction rate. Similarly, on the levels of depth of expression, these impediments may be patterned or sharpened as habitual response to be denial, circumstantiality and only superficial contact with the tests and identifications of reality. Then, indeed, one is contrasting this lack of realistic spontaneity with forms of participation that are emphatically sincere and honest. Here we have been thinking of quantity and depth, respectively, in interaction processes. For the third term, emotional valence or style, the illness polarity may disclose, for example, generally antagonistic, resentful or revengeful modes of interpersonal expression as typical. **Quantity, depth and style (or emotional valence) are, taken together, indices of the dynamics of an illness, and without this methodological organization or specific type of recognition, they have already**

been utilized in successful individual or group psychotherapy.

In respect to the interrelations of these elements, we have already noted that quantity *increases*, in affective stimulus or response, mark both the normative and the therapy group. Why is this? First of all, the affective stimuli are increased by the presence of several persons, but in addition, Borgatta and Bales learned that an individual typically tends towards his maximum rate of participation, modified for each by respect for the participation of others(2). In such striving behavior, there may be attempts at mastery, coping or reward-seeking since Keller found experimentally that those who initiate more discussion usually have more remarks directed to themselves(6). One learned also by experiment that groups arranged in circular (democratic) and intimate face-to-face patterns, without intermediate dominating figures, had both more interaction and superior morale as a result, Bales adding to this that the optimal size is the 5-person group. Miller has noted in the same context of small group research as Bales(5) that there are limits to our natural capacity for processing information, and that 5 to 7 units mark limits for visual and tonal stimuli, beyond which, at 8 or more, errors are common. (Compare 1 and 8.) Like the "span of immediate memory" or digit span tests, 7 appears to be a common limit.

In anthropology, both Murdock(9) and Lowie(7) have noted the universality of the "nuclear family" of parents and children, with kinship systems beyond this unit ignoring, restricting or creating and expanding such natural bonds through terminological notations. The nuclear group terms, however used—and the systems are several in world history—seem to run parallel to what is learned as to optimal size of human small groups though the actual individuals noted may far exceed the denotative kinship calculus used to categorize them. These data on human social organizations corroborate Bales' experimental data on the "best" size for maximizing interaction, except that here social organizational realities require humans to apply denotative kinship terminologies to often vast groupings, like clan relatives,

which exceed common intellectual capacities.

In group psychotherapy, one is dealing neither with normative family structures nor kinship variations. Even the abstractions of normative group processes, their quantitative and interaction findings must be taken together with considerations of the depth and style of individual communications as affected by group process or milieu. Thus, depth and emotional valences become somewhat more germane than the quantitative matters just reviewed. As with kinship systems in culture, though there are quantitative parameters indicated by the human limits for processing information, the information itself must be processed in patterns that are both personally and socially meaningful to the individual, or they become lost items in the business of living. In the serious work of role-playing, we can only assume or interpret roles that have some symbolic meaning and significance. As participants in any settings, group-oriented or individually expressive, role-conflicts are bound to impede action, emotion or cognition where they proceed from a splitting of values, meanings and goals. Both neurotic conflicts in which the struggle for a meaningful integration is still going on, and psychotic splits in which roles are curiously divorced from realities express the resultant states, the balances and imbalances, achieved in the service of role conflicts.

Group psychotherapy, according to Dreikurs, developed "almost incidentally" within psychiatry as a form of treatment devised "primarily to save time for the overburdened practitioner(4)." This is true, but almost equally there was a sense of generic similarity in problems of role functioning of classes of patients. Pratt, designated by some as "the father of group psychotherapy," discerned near the turn of the century a common problem in lower class tubercular patients connected with the isolation and sense of secrecy and shame connected with this disease, and its recognition and management. Accordingly, he used the group technique to create hope and give patients instruction about the management of tuberculosis. In the mental hospital, both Lazell and Marsh suggested total push methods in application to

schizophrenia, creating awareness that psychotics received benefit or "revival" from social interests and responsibilities. Adler applied the method in a more preventive sense to teacher and parent groups, again social role categories. (Compare items under 14, Pratt to Adler.) There is no doubt that current group psychotherapy in mixed groups has moved from these basic considerations, but it is as concerned today with role-conflicts exhibited within individuals and in groups as it ever was.

Dreikurs, in the article alluded to above (4), claims the "First Psychiatric Revolution" occurred with the introduction of humane treatment in mental institutions. The "Second, or Psychoanalytic Revolution" may be designated in his fashion as stressing early development and family experience (our emphases, M.K.O) in an era of "accentuated individualism" during which the psychiatrist "moved into private practice" (Dreikurs). Whichever aspect one stresses, the role of the physician, or the tendency to extend the interpretation of human relationships in the light of the patient's experience in the family, the latter were, as Dreikurs has noted, explored chiefly through individual psychotherapy following the recognition of the dignity of the person. It is easy to underestimate the importance of the psychological development of the individual in a family setting. In terms of our own methodological organization, we may note that the current emphases on small group dynamics—the typical sociometric and quantitative approaches to interaction—equally underestimate roots of family settings in typical subcultures of our times. While the quantitative approach to interaction may recognize human limits and potentialities for communication, such discussions of human optimum capacities are abstract unless both family and cultural role conflicts are explored. It is no accident that while group psychotherapy left the door open for Freudian and Neo-Freudian experiments in the quality or depth of expressive communications, it said less about emotional valences or basic styles of affective role conflicts.

However, besides the individual and the

group, and the concerns respectively for depth of affect and quantity of interaction, there are the affective patterns or styles of emotional expression which are chiefly an outcome of cultural role conflicts. Anthropology has long recognized these, without systematization in any given theory of personality, under the rubric of *acculturation*. The author, in working with Linton, and in focusing upon acculturation differentials where two cultural groups were involved in cultural change and interchange, noted in 1940 that larger cultural conflicts disrupting integration within a group resulted in poorer health, mental and physical, for the more rapidly changing culture representatives (10). This position was expanded in the framework of personality theory, in 1956, to include the nature of the culture, that is, its roles and role-conflicts in the setting of the pace and type of acculturation which existed. (Compare items, 10.) Just as *depth* of affect, a function of the quality of defenses, may govern the *quantity* of interactions or communications, so the experiences of early learning, affecting this depth, may influence the individual rates of response, in one direction or another. This formula states, in effect, that family experiences are crucial in determining what Chapple designated as normative interaction levels. Genuine group experiences, in 5-8-person groups, are apparently maturing or socializing in this sense since they provide the setting for normative levels to emerge while providing, even more than in individual therapy, the various parental, sibling and child surrogate figures which so often appear in such milieus. Consequently, when properly organized, they raise interaction rates on the average. It is presumed, when such symbolic substitutions for family figures are made, or when transference and countertransference phenomena occur with greater rapidity, that an advantage is gained by such symbolic introductions of family figures and amnesic experiences. No doubt, this is not only because quantitative rates are increased, but because *depth* and emotional *valence* or *style* are more involved. In the author's terminology, one is introducing the *wider context* and its *bind-*

ing conditions into the stage of affective recognition by inducing the patterned family and social influences (11).

These patterned family and social influences, to the extent they are acquired or transmitted by symbols and express roles, are by definition cultural. Since value orientations and motivational structures meet at this point, depth and style likewise converge. In dealing with symbolic, culturally influenced roles, psychiatry will do well to recognize that such behavior depends upon patterns larger than specific family contexts, but are ingrained and reinterpreted chiefly through family settings. The psychic economy requires some perceptual, affective and cognitive classification and denotation of experiences, much as kinship system, language structure, or ethical and valuational methods in a culture provide the simplifications that allow us to read the social and cultural map. Thus the individual products of any social and cultural influences are not coterminous with the adjustments found in society and culture generally, and we may speak of the uniqueness of an individual or the variance within an illness process. The limits to individuality or even "normalcy" for that matter are set by common experiences in family and extra-familial settings. Because social roles are limited by life-course associations, speech patterns, or styles of emotional expression, they are undergirded by value systems, motivations and culturally determined stresses. In addition to depth of affect, we can ignore style of emotional expression and role-conflicts only at our peril in psychotherapy. Both influence quantity and depth of emotional communications. In short, the wider context of emotional valence and culturally determined roles influences the depth and quantity aspects of psychopathology.

Because of space limitations, only two examples may be given. A Puerto Rican psychiatrist, Torres-Aguilar, reports his observation of relatively high prevalence of catatonic outbursts of a hostile and aggressive sort in schizophrenics of lower class background. Schizophrenics with paranoid reaction, centered in confused sexual identity, are likewise typical and the paranoid elements are freely

expressed. In the neurotic categories, classical hysterical conversions, attacks of fainting more commonly for women, and freely expressed hypochondriacal complaints seem more marked in urban Puerto Ricans of the island than in most modern cultures. Today, such traits are seldom emphasized in reports from other urban scenes. Our observations on Puerto Ricans on the mainland, first generation, run strictly parallel. In fact, all norms of emotional expression and display of affect are more noted among these people. There is, as a cultural pattern, little inculcation of guarded affect, an emphasis upon *soma* and interest in sexual detail, great concern about health, and currently much disturbance occasioned by a shifting, particularly in urban scenes, of the social and economic role positions of the two sexes. Dr. Torres' (15) and our own observations run parallel on finer details than can be given here.

Similarly, the author studied South Italian and Irish schizophrenics of 3 generations. The Italian migrants and their descendants appeared to have a larger proportion of patients having catatonic outbursts of the hostile and destructive sort, while the classical reactions of paranoid type were found in the Irish patients, varying considerably from Puerto Ricans in guardedness, for one feature. All had the "official diagnosis" of schizophrenia, but the differences were vast indeed. In discussions with such patients singly, or even in group situations on the ward, it was helpful to anticipate such variations in emotional patterns and discuss them with the patient on neutral grounds of cultural affiliation. Viewing quantity, depth and style of emotional communications as an integrated balance of personality, one avoids a moralizing, condemnatory or judgmental tone in favor of satisfying discussions of social and cultural roles. The neutral grounds of cultural interest and affiliation provide the wider context of family background and individual experience. Elsewhere, we have called this method of inducing the wider context as the initial step, "cultural push therapy" (10).

In our experience, cultural reference al-

lows for a more delicate processing and ventilation of experiences in therapy. The neutral grounds of cultural interest provide more motivation for achieving perspective on social role positions. Any relationships, going in a series from man to fellow-man (social relations), man to family, and finally degrees of self-awareness, figure in cultural discussions. Even man-to-nature relationships are relevant. Ordinary guide lines of cultural experience give perspective and provide the same life-course phenomena and family roles that are the typical interest of patient and therapist alike. The therapist's acceptance of a person's culture is therefore the first step in his understanding of the family and the individual. For the patient, similarly, self-esteem and self-awareness may well depend on the rapport set up in such interchanges of cultural meanings and implications. In the studies of schizophrenics, Italian and Irish, alluded to above (12, 13), the entire structure of the illness and of current defensive balances depended upon the emotional valences built up in a sub-cultural setting and in a family over time. Quantity and depth of emotional communications varied notoriously with the course of illness, but style of emotional expression, far more crucial, varied with the culture and the role conflicts introduced between generations.

In group psychotherapy, there is opportunity *par excellence* to build up cultural awareness and respected identities. These, in turn, represent a gain, or the occasion, for developing individual perspective on self-images, and empathy for the products of others' lives. For the therapist, who must guide the total process, an awareness of the differing family structures and role conflicts of various cultures and subcultures will provide a key to emotional valences of persons coming from various backgrounds.

Apart from quantity of human interaction, the varying depths and styles of emotional expression point directly to typical roles, which need better understanding and depiction, since these roles, in turn, represent the sorting into modes of action of values, aspirations, motivations and typical stresses. The firm texture underlying conduct is far from biological need alone. Until such keys to behavior, normative and aberrant, are used, we cannot enter into a world of meanings which are otherwise only the sealed-in aberrations of troubled minds.

NORMAL DEVIATIONS FROM REALITY

CLAUDE C. BOWMAN, Ph. D.¹

"Reality" is a very ambiguous term, one that immediately raises a host of issues. Gregory Bateson has contributed to clarification here by outlining 5 definitions that can be found in psychiatric thinking(1). In one sense the word denotes the external world as perceived by the senses. This definition contrasts reality to fantasy and projection, but the term is often used in a contrary manner to denote the very subjectivity that is rejected by the first definition, reality referring to the individual's private world. A third definition involves awareness of one's idiosyncratic views and an ability to transcend these individual peculiarities in the interest of greater accuracy and effectiveness. Fourthly, the word appears in the phrase "the reality principle" which is commonly contrasted with the "pleasure principle," thereby suggesting that reality is unpleasant. Finally, reality is often contrasted with phenomena of magic. In this sense it is based upon the conceptions of science.

The relevance of these 5 definitions to the means and ends of psychotherapy is a complex subject that lies outside the competence of the sociologist. Here our purpose is to show that certain degrees of unreality, far from being a handicap to normal men and women, actually contribute to the maintenance of their morale. We shall maintain that the biases favorable to morale are not occasional deviations from normal thought and action but are in fact indigenous to culture and social living.

Now it is evident at once that a particular definition of reality is implicit in this statement of purpose. Let us be more explicit. In the discussion that follows *a sense of reality refers to conceptions of the social environment and of oneself which satisfy the highest standards of objective accuracy.* It may be noted that this definition touches upon the first, third and fifth definitions developed by Bateson. From our point of view realism stands in contrast to the conventional biases and illusions of man's social life.

¹ Department of Sociology and Anthropology, Temple University, Philadelphia 22, Pa.

Immediately the question will be asked, "And who shall decide what is objectively accurate?" Are we not hopelessly caught in the toils of biases both subjective and collective? Actually the dilemma is less formidable than might seem to be the case at first glance. Once the fundamental value of special competence is granted, it becomes relatively easy to establish adequate standards in the complex task of determining reality. An assessment of sociological data and of opinions about these data can be undertaken by scientific experts whose knowledge and judgment tend to approach objectivity. Just as the psychiatrist possesses special competence in judging degrees of reality or unreality in the patient's mind, so the social scientist is equipped to determine not only the nature and extent of distortions in collective thought but also their social causes and effects.

The following examples represent common types of deviation from reality that can be found in American society today. Of course, it is not suggested that *everyone* exhibits these tendencies, but merely that the types of thinking described here are sufficiently common to warrant the attention of the sociologist

NATIONAL CULTURE

The concept "ethnocentrism" serves to emphasize the amount of unreality existing in all cultures. Each folk or nation tends to consider its ways as best and measures other cultures by its own yardstick. The achievements of the past, the rightness of current practices, the greatness of their destiny—such grandiose views are widely supported by the members of a given society. Informal and formal teaching by adults give sanction to the *mores* and this process of indoctrination is reinforced by habits formed in the daily round of activities. In a sense it may be said that, when one member lies—in an approved direction—the rest will swear to it. Thus, each culture generates and preserves a set of biases considered appropriate to its

ongoing life. The "strange," "irrational" or "immoral" ways of other people are viewed with amusement or alarm by the vast majority who, by these reactions, give emotional sanction to accepted patterns of living. Even in the most liberal cultures open-mindedness in regard to basic *mores* is sometimes tolerated but never actively encouraged. Australian aborigines, Japanese, Americans, and all other peoples are expected to follow the fundamental beliefs and values of their respective cultures.

Except during periods of upheaval and rapid change, deviations from cultural orthodoxy are not frequent enough to constitute a serious threat to group integrity and morale. The majority have little desire to run athwart the conventions but grow up to believe what they are supposed to believe. Some sacrifice of reality seems a small price to pay for social approval, especially since most people do not understand obscure issues of reality and unreality and, consequently, are wholly unaware of any "sacrifice." It is true that the more democratic nations do permit critical public discussion but even in these countries the distorting influence of patriotism is quite evident.

The following illustrations bear upon this point. We in the United States want to believe in the essential soundness of our family system, business institutions, schools, system of government, and our other institutions. Out of this patriotic faith the citizen builds loyalty and morale for peace-time pursuits as well as for times of war. It has come as a shock to many to learn that the "backward" people of Asia believe that they are just as important as the United States of America. In our naive way we tend to think that everyone the world over accepts the goodness and greatness of our country as a permanent feature of the universe. We firmly believe that our actions are ever rooted in high moral principles and feel hurt or irritated when our policies are examined by other countries for dollar diplomacy. Moreover, when certain powerful leaders of Asia prefer to avoid clear cut alignment with our side in the cold war, we tend to react with adverse criticism, if not open denunciation. In such ways patriotism may preclude an adequate apprecia-

tion of the problems of Far-Eastern countries.

On the domestic front one of the most noteworthy examples of unreality is the refusal of the general public to face the grim possibilities of war. A naive observer, uninitiated in the processes of illusion-building, might surmise that the development of atom and hydrogen bombs, not to mention bacteriological warfare, would lead our nation to give this problem top priority. But what has been the situation during the post-war years? Civil defense gets small public attention and small public subsidy. Urban re-development proceeds largely on the basis of pre-atomic thinking, increasing congestion rather than encouraging wider dispersal of the population. And what of the private efforts of individual families? Conscientious parents, striving to establish a good home for their children, will look amazed when you ask whether they have made plans for protecting their families in the event that a major war should break out. It is just too horrible to think about.

This is conventionalized escapism, to be sure, but it is the present thesis that such deviations from reality are important to adjustment. What can the individual citizen do, in the face of technological progress and institutional lag, except to indulge in a certain amount of "ostrichism?" Somehow or other he must carry on his daily affairs *as if* such threats did not exist. Perhaps physicists and engineers are perfecting a bomb five hundred times more destructive than those dropped on Japan in 1945 but right now the baby must be fed, the boss is calling for that report, or a party is being planned. The maintenance of morale seems to require that we avert our gaze from the grim possibilities of destruction, and hope for the best.

It is clear that the optimistic spirit has pragmatic value for individuals and groups, signifying faith in purpose and expectations for success. Yet optimism operates as a defense mechanism, the optimist seeing only what he wants to see. Aspects of the total situation that do not fit his orientation are ignored or, if recognized dimly, pushed aside before they emerge into full consciousness. Those holding important administrative positions may expect subordinates to distel their

doubts. Others seek reassurances from family and friends. In numberless ways we support each other in rose-colored views of reality and express disapproval of those who try to puncture the illusions by which we live.

The origins of American optimism must be sought in history. This frame of mind developed readily in a new country, rich in natural resources, expanding industrially and agriculturally, growing in size and power as more and more young, ambitious immigrants came from Europe. An optimistic outlook was an essential ingredient of the enterprising spirit of the 19th century and many believe that it is just as essential today.

SPECIALIZATION

Some degree of distortion appears to be inherent in the outlook of the specialist; indeed, in folk humor, specialists of all kinds are belittled because of their biases and lack of common sense. Now the sociologist realizes that various institutions (economic, political, educational, religious, recreational, etc.) in modern society are characterized by an increasing proliferation of structure and function, leading to individual careers which are more and more specialized. Yet, in the midst of this growing division of labor, the individual tries to preserve a sense of his significance and worth. In some occupations, such as routine tasks of a large factory, it is difficult to do this; but even in careers of higher status there is a constant struggle to preserve a sense of personal significance. In this effort a full and steady sense of reality may be a distinct handicap.

The academic profession may be used as an illustration. As subject-matter in various fields of knowledge has broken down into more specialties, scholars tend to concentrate upon knowing more and more about less and less. Under these circumstances it is easy, and perhaps necessary, to over-value the particular segments of knowledge where one's own proficiency lies. Such over-valuation seems integral to professional adjustment in the academic world as it exists. He who plays the game according to the rules is likely to gain promotions, offers from other institutions, an impressive list of publications, and other advantages. College presidents may deliver stirring addresses criticizing the narrow

specialist, and a few professors, particularly in obscure colleges, may resist the trend but these instances have little effect upon major tendencies in the academic profession. (In a few universities the embryonic professor can now take broader graduate programs in the social sciences or humanities but it remains to be seen whether this type of curriculum will have a significant impact upon Ph. D. education.)

It is the function of college administrators to construct a broad overview of institutional purposes. Insofar as administrators fulfill this function, they do bring a more realistic perspective to bear upon major decisions, decisions compounded of many ingredients contributed by various specialties both within and without the institution. Yet it cannot be assumed that top administrators are consistent realists. The ego feelings of these leaders are likely to be deeply involved in their organization. Such persons look upon the enterprise as peculiarly theirs; its successes and failures are felt more keenly, its good name is related to personal pride, and faith in the institution is an extension of the leader's faith in himself. Thus, the typical college president wants to believe that the collegiate *status quo* is essentially sound. "Our college is doing an excellent job, the faculty is capable and contented, the students eager and appreciative," he tells himself optimistically. Like other practical men of affairs he accepts the reality principle only so far as it is practical to do so.

Higher education has been used as an illustration but the same processes are evident in other fields. Within the professions there are at least 3 conditions leading to occupational bias. 1. A long period of preparatory education, involving time, effort, and money, leads the professional person to place a high valuation upon his achieved proficiency. 2. Colleagues in the same field tend to support each other's evaluations and rationalizations. 3. Professional organizations also contribute to morale by holding conferences and performing various rituals designed to give further sanction to group purposes. If, out of this multilateral process of indoctrination, the individual begins to magnify the importance of his chosen career, it should occasion little surprise.

SOCIAL CLASS

A common illusion is that there are no social classes in the United States. Many like to think that one person is just as good as another in this democracy where "all men are created equal." Now it is true that social stratification in this country does not consist of historically fixed categories sharply separated from one another by insurmountable barriers; instead, we have an "open class" system. Nevertheless the factor of status is very important in social relations. Groups on a vertical scale show relative differences in manners, morals, material comforts, occupations, residences, and civic participation from those of a higher or lower status. For this reason we may properly speak of class sub-cultures.

People of various social levels tend to develop and defend an outlook on life that is functionally appropriate to their particular position. Some in the highest strata hold to the complacent opinion that the cream of society inevitably rises to the top, ignoring completely such influences as family background and inherited wealth. That broad segment of society known as the middle class commonly considers itself to be the salt of the earth. These people assume that all "sensible" folks think as they do about politics, careers, family life or education. The lowest strata also have their special ideological slants. The rich and powerful are "lucky," the poor "unlucky." Some will even assert that the higher classes operate on a lower moral plane while they are "poor but honest." To be sure, such face-saving rationalizations may contain elements of validity—but elements of unreality too.

Since the class-bound person seldom carries on extensive communication with those of a higher or lower status and since most of his associates are also class-bound, he finds it easy to retain these parochial views. In this way certain distortions are supported by the various classes—with favorable effects upon morale.

MINORITIES

Racial and national minorities may also show a reluctance to face reality. An ambitious Negro may insist upon believing that

"there is plenty of room at the top," minimizing the handicap of prejudice. And why not? Assuredly it is not practical for him to dwell upon such handicaps. Similarly, Jewish men and women sometimes wear blinders so that they will not see anti-semitism. Indeed, some are sharply critical of other Jews who insist upon taking notice of prejudice. Again, in the interest of morale, why look unpleasant reality squarely in the face?

LOVE AND FRIENDSHIP

Through the ages it has been said that love is blind. Today it is fashionable among family sociologists to decry romantic illusions and urge a more realistic point of view. To some extent the new realism is salutary, for it represents the substitution of informed intelligence for traditional ignorance and mysticism. Yet the dynamics of teachers and textbook writers who criticize romanticism will bear further scrutiny. Perhaps the disillusionments of middle age are involved here. Also, a puritanical value system may lead such persons to emphasize the gospel of work and, correspondingly, to distrust those pleasures that detract from the serious business of "getting ahead."

From whatever sources it arises, this "realism" fails to understand that, in heterosexual love, the reality principle is at times "more honored in the breach than in observance." The dependent person, seeking security in the love of another, may magnify the other's strength and dependability because of this inner need. Other idealizations may concern beauty or achievement or ethics. These elements of unreality are not necessarily harmful; in many instances they are distinctly advantageous to both persons.

Parental conceptions of children can be equally unrealistic. Parents often have exaggerated notions concerning the capacities and achievements of their children—as every teacher knows. Conventionally we come to expect a certain amount of illusion on the part of parents and even view it sympathetically. Of course, there will be disappointments when such conceptions depart too far from reality but, within limits, sentimental biases constitute a bond of cohesion in family life.

on a lower plane of emotional attachment. This principle is evident in friendships. We tend to be somewhat unrealistic about those whom we love, and we tend to minimize those who criticize them. Perhaps many of us play politics where friends are named: we recommend them for positions because we like them and not because they are in the best light of reason, the best qualified. Such biases are given open approval in a culture that stresses the value of friendship.

At the same time friends are expected to contribute to one's own morale by praising achievements and minimizing failures. In this way favorable self-conceptions are maintained and the harsh impact of reality is softened. Thus, it may be said that a person's friends are part of a pleasant conspiracy to keep him in good spirits.

REFERENCES

This leads to a final word about self-attitudes and mental health. According to the definition given earlier, realistic appraisals of one's self are based upon objective assessment of a whole range of relevant factors. On the other hand, the maintenance of morale may require some degree of emphasis upon ego-gratifying factors in the total situation of the person and a minimizing of ego-

It may seem to reflect a very serious, if not alarming, situation and encouraged by the evidence of pre-adolescence. This is a complex question with many dimensions and the following highlights the different kinds of phenomena which are currently associated with it.

— 11 —

The foregoing provides a contrast with several dominant group theories in contemporary social and clinical psychology which stress agency. The author is not in agreement with those who believe that such agency being given to people gives them the freedom to act or to respond and act. It is the present theory that individuals and groups naturally develop values consistent with their standards and purposes. This tendency involves elements of morality, but it fosters mental health and not necessarily society.

RELATIONSHIP BETWEEN SOCIAL ATTITUDES TOWARD AGING AND THE DELINQUENCIES OF YOUTH¹

MAURICE E. LINDEN, M.D.²

INTRODUCTION

It must be stated at the outset that in effect this paper adds another imponderable to already extensive lists of factors contributing to youthful misbehavior. It is to be hoped however that it will not be classified in that group to which Edwin J. Lukas(1) refers when he states, "Each so-called 'preventive' enterprise has its own concept of causation to which it adheres with a tenacity which would evoke more admiration if the concept were more valid."

At the risk of oversimplifying a serious and complicated field of inquiry the writer is emboldened by a group of observations having a uniformity that urgently suggests they may well be facts:

1. Certain social changes predominantly in western societies have taken place during recent decades which constitute a shift in emphasis toward children's needs, resulting in the 20th century's often being referred to as "The Century of the Child"(2).

2. Concomitant with unprecedented population increases in the late mature categories there is abundant evidence of increasing dependency by the elderly upon public institutions, often associated with diminishing acceptance of family responsibilities toward the elders. A factor of elder-rejection plays a prominent role in such transfer of obligation (3).

3. Psychiatric clinicians have noted a widespread fundamental change in the clinical picture of the neurosis, with diminishing numbers of the classic neuroses but an overwhelming increase in character disturbances in which "personality" and "symptom" are practically indistinguishable(4).

4. Increased attention in Western culture during recent years has been drawn to the problem of youthful misbehavior. The Di-

rector of the F. B. I. in the United States has issued a public statement to the effect that there has been a definite increase in juvenile delinquency rate disproportionate to population growth.

5. There is fair evidence that countries and ethnic groups having a low juvenile delinquency rate are those whose cultural atmosphere reflects veneration and, or at least, acceptance of the aging and the aged. Agreement is general among sociologists and anthropologists(5) that elder-veneration, tradition-boundness, and a low rate of youthful delinquency are frequent concomitants.

The present thesis suggests that the foregoing social findings are mutually interrelated in a psycho-social equation; that a cultural factor of elder-esteem or elder-discard enters intimately into character formation in the development of personality; that the characterological attributes having to do with attitudes toward the aging are decisively linked to value systems governing moral and ethical principles and conformity; that devaluation and discard of the late mature generations are real social hazards potentially damaging to children; that the absence or distortion of a concept of social authority in which the status of the elder plays a significant role contributes importantly to a widespread looseness, waywardness, and rebelliousness of youthful behavior; and that without losing any recent social gains it is possible to influence favorably some aspects of the character formation of youth by restoring to the process of aging a connotation of authority and an implication of social reward.

THE CENTURY OF THE CHILD

Today the long overlooked needs of children have begun to receive attention. What is often forgotten, however, is the tendency of human nature to overcompensate for its defects, and to concentrate with almost fanatic enthusiasm on newly uncovered areas

¹ Presented at the First Pan-American Congress on Gerontology, Mexico City, September 18, 1956.

² Director, Div. of Mental Health, City Hall Annex, Philadelphia 7, Pa.

of social omission. The unfortunate consequence is the impoverishment and neglect of other sectors of social endeavor.

There is abundant evidence that the qualities of youth are the preponderant social goals. Note the prevalent anxiety regarding chronological age. Witness the omnipresent emphasis on newness, sleekness, freshness, mobility and change. But, in particular, observe the everyday tragedy of people moving blindly toward the later years with their inner vision arrested deceptively upon a fond mirage of the irrecoverable past.

Mankind hardly deserves any kudos for protecting and guiding its own helpless developing neophytes. Such are the functions of inherent biological drives. But the severe test of a civilization is found in its capacity to advance beyond the simply biological, and to create systems of group living in which personal welfare and meaningful existence are every participant's birthright.

We cannot escape the present reality in which the qualities of the young side of life are upgraded.

ELDER-REJECTION

Today more people remain healthy, live longer, and reach later maturity than ever before in history. The implication of social progress is tempered by certain other parallel disturbing facts: the tremendous number of older people for whom admission is sought in mental institutions; the mushrooming nursing home enterprise; the immense proportion of elderly on public assistance rolls; the widespread absence of social and recreational provisions for older folks; the marked increase in hospital occupancy by the chronically ill; the large numbers of solitary and bewildered aged existing in substandard living conditions, passing time aimlessly awaiting the end.

Certain exigencies of urban living plus a deep psychological predisposition to regard aging as unattractive(6) have forced ever greater numbers of families to relinquish a time-honored responsibility and divest themselves of the duty to care for their older members. The closing decades of the century may mark the *Era of the Nursing Home*.

That the windup of a life in the segregated quarters of some types of institution constitutes an empty and uninspiring goal can hardly be questioned. And there is logical foundation for the conclusion that all forms of social and psychological rejection of the elders are incorporated in the self-concept of the aging and eventuate in self-rejection that heralds personality regression and disorganization.

More important still are the effect of attitudes on the character development of oncoming generations.

CHARACTER DEVELOPMENT AND DISTORTION

The formerly common classic neuroses, such as hysteria, obsessional and compulsion neurosis, were based on rigid prohibitions, suppressions and extravagant punishments. It has been said(7) that "the inconsistency of the modern neurotic personality corresponds to the inconsistency of present day education. The change in the neuroses reflects the change in morality."

Character may be defined as an individual's habitual mode of responding to demands from various sources within and without the psyche(8). It is socially determined(9). The concept of character is closely analogous to the concept of "ego" as formulated in modern psychiatry. The ego has many functions, among them being the mediation among the demands of the instincts, the pressures of conscience and certain internal automatic repetitive tendencies. Even in greater measure the ego, or character, is called upon to integrate intimately into its structure the innumerable surrounding social stresses including the mores, ethics and group attitudes.

Uncomplicated observation suggests that the perpetuation of social and cultural values, the development and support of moral and ethical judgments, the evaluation and maintenance of the substance and resources of knowledge, as well as a related assortment of intellectual activities are the inherent functions of the mature mind. Man's concept of God and his ideal representation of the elder are the authorities for systems of discipline. They serve also as the source of power and impetus to effect a realization of social plan-

ning, to create and maintain systems and modes of social welfare, and to preserve the thread of philosophical continuity that runs through the basic principles of a civilization.

The development of an ideal social conscience in a child is consequent upon the success of psychological mechanisms through which he incorporates the best personal and social symbolic images available for identification. The inspirational goals that antecedents personify and the regard of the child for his elders figure significantly. The child also will absorb the inconsistencies, the unsolved problems, the prejudices and antipathies of his educators. As Johnson(10) has pointed out the child incorporates into his character factors operating from the unconscious structures of the minds of his educators.

The maintenance of the parent and grandparent ideal as the source of wisdom, goodness and love, judiciously associated with adherence to principle is significant in the creation of an ideal social character in the child. The socially oriented structure of his character becomes weakened if there is need for rebellion against his educators. In most individuals rebellion against the elders represents a seeking after independence and personal expression. In an ideal society, regardless of individual rebellion, an aura of respect for the elder and elder authority would remain constant.

The social inconstancy of parental character, a cultural rejecting attitude toward older people and a generalized mitigation of their social authority are readily absorbed in the character formation of the developing child.

The older generations, by virtue of psychological and physiological aging processes, cannot long endure the pressures of downgrading and hostility to which they may be exposed and their diminishing resistance may progress toward social powerlessness. Such debasement of the elder in the role of and as the symbol of authority tends to diminish the meaningfulness of all social authority. Youngsters may then incorporate into their own character an attitude of regarding aging mainly as decline, decrepitude and loss of purpose. When this happens, the child may

establish himself in his own eyes as a potent and autonomous authority.

YOUTHFUL MISBEHAVIOR

The decline in parental influence which parallels the decline in social authority of the older generations is currently reflected in a widespread need for an increase in police authority. That is, wherever family control is weakened, society finds it necessary to increase public and impersonal methods of behavior control.

This is not the equivalent of judicious parental control. Policing agencies are generally regarded as restrictive and punitive, not as loving guidance and training agencies. The immature character finds the presumed punitive agencies challenges for rebellious and hostile acts. Thus, what in ideal family life would be beneficently controlled rebellion, in the social setting becomes open conflict.

Since policing services are looked upon as law enforcement instruments the distorted character's behavior may tend to avoid only that which is illegal in order to remain clear of the law. Such technical conformity permits a great latitude for actions that are socially opprobrious but not strictly illegal, and nefarious and discourteous practices of all kinds become an increasing reality. There is real social danger and potential damage to children in a social setting that demerits the elders.

Impressionable youth lacking adequate older objects for consistent identification may develop an enormously exaggerated belief in their own capacity to destroy tradition. They may disregard the mores, flout ethics, and discard historically established qualities of discipline.

Statistical tabulation(11) of juvenile offenses reveals a high incidence of acts of furtiveness and stealth or incorrigibility and ungovernability. The minority of problems are in the area of passion or bold aggression.

An overdramatized and grandiose self-concept in the young contains the danger of contagion. The illusion of being "master" is communicable among the immature. It is a deception that may be basically responsible

the revolutionary abolition of tradition by an entire social group and the acceptance, if even only temporarily, of a neo-devotion created on a substructure of personal aggrandizement, impulsiveness and hedonism.

ELDER VENERATION

A lack of leadership uniformity which seems intimately bound to degradation of the elders furnishes fuel for hot rebellion in younger persons whose drive toward unwise autonomy is thus reenforced. Within the family a set of attitudes is often created in the young as they observe the now hidden, now open, brutality practiced upon their grandparents by their parents. "As the child incorporates in himself the image of his parents as part of his internal organization he is absorbing among other things this very pattern of sadism against the senior elder. Thus is guaranteed the fact that the vicious cycle of elder rejection will remain unbroken generation after generation" (6).

Tradition-bound societies, some of which are exemplified in the ancient Chinese, Hebrew and Indian cultures, can boast of a low rate of juvenile delinquency. The common denominator in tradition-boundness is respect and veneration of the elders. A return to the "good old days" with increased irrational authority of the parents and elders, it is said, would help materially in reducing the psychological breakdown that eventuates in senility, as well as reducing the rate of youthful misbehavior. However, many social scientists and community leaders would decry any retrograde cultural change that would imply loss of any social gains enjoyed today.

Thus there is need for social planning so designed that the late mature generations are reassigned social recognition as well as the comforts and rewards to which human nature aspires.

Within the family the parents cannot relinquish their affectionate and responsible educative role without insidiously affecting the character formation of the young; and the foundation for good government and good citizenship is to be found in the proper structuring and functioning of each family.

If the hypothesis (12) is accepted, that

normal maturation into the later years means increasing altruism in the older mind, then it is possible to conceive of a society in which collective social authority is irrevocably linked with elder-veneration without the necessity for sociological retrogression. It is the very nature of benevolent elder authority to employ its power not to command and dominate, but to develop leadership among oncoming generations, and to serve as adviser, consultant and coworker.

CONCLUSION

In the awesome network of social forces that relate to character and behavior distortion the hypothetical factor herein presented concerns itself with but one thread, perhaps a guyline. There seems to be a commonsense logic in the viewpoint that degradation of the elder role-model of social authority is paralleled by an increase in arrogance and wilfulness in the young.

The fact remains that aging in our culture is generally unattractive and unrewarding. A newspaper supplement recently stated the case succinctly, "the world is made for youth and youth is the time for fun." Can we expect the young to make provident and prudent psychological preparations for the advancing years, when the later period is so often seen in threatening aspect.

Desirable character formation in the young requires that the group character of a culture present a social atmosphere of dignified elderhood in which symbolic authority is implicit, an authority enriched with warmth, humanism, and charity, yet firm in its leadership, independently motivated, and oriented around group principles.

Nature has endowed youth heavily with a capacity to achieve its own rewards. Aging needs social support. If the rewards of youth are to be wisely invested to insure that lives are well spent, then the elders must be reinstated in their time-honored position as brokers in experience and consultants in living.

FOLLOW-UP STUDY ON THORAZINE TREATED PATIENTS¹

ELSE B. KRIS, M. D., AND DONALD M. CARMICHAEL, M. D.²

Modern drug therapy has brought about a considerable increase in the number of patients returning to the community. While a great deal of knowledge has been accumulated on the effect of chlorpromazine on hospitalized patients, very little was known about whether the achieved remission of symptoms would be a lasting one, whether maintenance therapy was indicated and if so for how long a period. Last but not least, there was understandable concern about possible effects of long term chlorpromazine administration.

To study these questions a unit was set up with the purpose of keeping a limited number of patients released from mental hospitals in the New York metropolitan area under close supervision.

This report deals with 160 patients who were kept under close supervision for one full year. They came to the Manhattan After Care Clinic in response to special request: the directors of several New York state hospitals in the metropolitan area had been asked to advise patients, who had shown improvement after Thorazine treatment, to report to the clinic on the day immediately following their release from the hospital.

There were three different groups of patients under control:

Group I: Consisted of 57 patients who, during their hospital residence, had been treated with Thorazine and who, after withdrawal of the drug, maintained their improved mental condition and consequently were released from the hospital.

Group II: 82 patients who, during their hospital residence, had received Thorazine and who required to be kept on a maintenance dosage of the drug.

Group III: 21 patients who had been released from a mental hospital 1-4 years ago, had adjusted well until recently, when they began to show symptoms of beginning re-

lapse and for this reason were brought to the clinic in an attempt to prevent their readmission to a mental hospital.

Patients in all three groups were seen regularly once a week. Home visits by a social worker were made occasionally.

Group I: The 57 patients were between 18 and 63 years old. They were diagnosed as follows:

- 25 Schizophrenics
- 16 Manic-Depressive, Manics
- 2 Psychosis due to Alcohol
- 1. Involutional Psychosis

Nineteen of these patients have had a hospital residence of 3-18 months and had been released on Convalescent Care after several weeks of observation following withdrawal of the drug. Thirty-eight patients in this group had been hospitalized for 2 to 10 years. Sixteen of these patients, who have had such a prolonged hospitalization, had to be placed again on Thorazine a few weeks after their release on Convalescent Care as they began to show restlessness, irritability, anxiety and other signs of returning psychotic manifestations. In 2 of these patients, the return of symptoms came about so rapidly and so fulminantly that they were returned to the hospital immediately. The other 14 patients are now on maintenance dosage of Thorazine and are again symptom-free.

Group II: These 82 patients ranged in age between 17 and 68 years. They were diagnosed as follows:

- 48 Schizophrenics
- 19 Manic-Depressive, Manics
- 4 Psychosis due to Alcohol
- 11 Involutional Psychosis

Among these patients, 23 have had a hospital residence of between 2 and 10 years and 15 have had 2-9 hospital admissions of various duration. Eleven patients in this group had to be returned to the hospital. For better evaluation of circumstances leading to

¹ Read at the A.P.A. Regional meeting in Montreal, Nov. 8-11, 1956.

² After Care Clinic, 2 West 13th St., New York City.

these returns, it seems important to consider the facts in some detail.

Patient, A.H., diagnosed as Manic-Depressive Psychosis, who, on his initial visit to the clinic on the day following his release from the hospital, had been found to be in a pronounced hypomanic state, became assaultive the next day, was taken to the City Jail and from there was returned to the hospital.

Another patient, G.C., diagnosed as Dementia Praecox, Catatonic type, who had been hospitalized for 8 years and who, on her initial clinic visit, was found to be highly confused was returned to the hospital by the family on the day following her clinic visit.

Four patients had not taken the drug as was found out after their return to the hospital.

In 5 of the 11 patients in this group, who were returned to the hospital, the social situation present was extremely unfavorable and in at least 2 cases, it is felt that better placement in the future could make attempts toward social reintegration more successful.

All patients in Group II were kept on a maintenance dosage of Thorazine ranging between 50-150 mgm. daily. They received, at first, the maintenance dosage prescribed at the hospital. However, it was found to be necessary to change the dosage in accordance with the individual requirements, either increasing or lowering it.

Though several patients were reported to have had some side effects from the use of the drug while in the hospital, the only complaints voiced since their release from the hospital were drowsiness, sleepiness, constipation. As many of them stated that these side effects interfered with their work and as it was felt that drowsiness, in particular, might eventually be the cause of some accidents, the dosage was, where possible, adjusted in such a way that the drug was given in one single dosage at bedtime. Where it was felt that an additional dose during the day was absolutely necessary, the patients were admonished to take the morning medication after breakfast and to rest for about one-half hour before going to work. The only side effects occasionally seen in this group were mild skin rashes which easily responded to treatment with hydrocorton ointment.

The importance of *variation* in the maintenance doses administered to each individual

patient can be best illustrated in the following two cases:

Patient, A.T., got along well on a maintenance dosage of 100 mgm. Thorazine given at bedtime. She was working, and as her parents with whom she lived were both ailing, she was proud of the fact that she was now not only able to contribute to their actual support, but could also afford some luxuries for them, like a television set which she had bought on installments, etc. One day, her boss had found out that she had been a mental patient and on the ground that she had concealed basic information when applying for the job—she was fired. She became very upset and when seen at the clinic was advised to stay at home for a full week and was placed on 300 mgm. Thorazine (given in 3 equal doses) daily for 2 weeks. During this time, she was visited by the social worker at her home several times in addition to her weekly clinic visits. At the end of the second week, the dosage was again reduced to the previous level of 100 mgm. daily. At the end of the third week she had found another job, and is maintaining her level of adjustment up to date. It is felt that only this quick increase of Thorazine dose prevented complete relapse in this as well as in other similar cases.

Patient, P. O., an alcoholic, who had received 200 mgm. Thorazine daily, complained that he began to feel on the verge of drinking again. The dosage was doubled for 2 weeks and to date, several months later, he has not reached out for the alcohol as yet, and was able to hold his job, while receiving 100 mgm. twice daily.

As patients began to show signs of restlessness, tension, return of symptoms of anxiety, insomnia, failing appetite, it was found that an increase in the chlorpromazine dosage over a few days followed by gradual decrease to the original amount of the drug seemed to control these symptoms so that the individual continues to function on a satisfactory level. As family problems arise and social or economic stress becomes severer, the dosage of the drug seems to require adjustment. It was noted that frustrating life situations precipitate recurrence of symptoms, which if not checked quickly tend to lead to complete relapse.

Group III: This group consists of 21 patients who had been released from a mental hospital several years ago. Five have had several hospital admissions. Only one of them has had Thorazine while in the hospital. As they began to show return of psychotic symptoms, either the patients themselves or their families contacted the clinic asking for advice and assistance. Four of these patients came to the clinic only after

having consulted their family physician who had given them 25 mgm. Thorazine daily for 1-2 weeks and as the symptoms became worse instead of better, they resorted to calling the clinic. As all the laboratory tests had been found normal, they were all placed on 100 mgm. Thorazine three times daily for 2 weeks. During this time, they visited the clinic once a week and were seen by the social worker in their homes twice each week. All but one patient tolerated the drug well and after gradual reduction of dosage are presently found to be symptom-free again. Eight are no longer on maintenance dosage and have gone back to their jobs. Two patients in this group had such a rapid relapse that the symptoms could not be checked by Thorazine treatment on an ambulatory basis and they had to be admitted to the hospital.

The case of A.A. seems to be worthwhile reporting here. He has been hospitalized on several occasions and when released from his last hospital residence 2 years ago, had been in a state of defect, but was able to function on a primitive level, working only in his father's store. When the family called the clinic, it was stated that the patient has reached again a very disturbed state, refused to take care of his personal needs, did not come to the family meals, was withdrawn, did not talk at all. When brought to the clinic, he was found to be completely disheveled, his hair reaching down to the shoulders as he had refused to see a barber. He was mute and resisted any attempt to get him to answer simple questions. After 2 weeks of 300 mgm. Thorazine daily he was alert, talking, pleasant, clean, he had a haircut, smiled and answered questions readily. The dosage was gradually reduced and presently he is, for the past 11 months, on 100 mgm. Thorazine at bedtime only. During this time, he has applied for a job on his own accord and is working as a garage helper. He spends his free time going to the movies, visiting friends and going to parties. He has recently made a vacation trip to Florida with some friends and is talking about his first experience of flying with great delight.

One patient in this group did not tolerate the drug, but developed symptoms of an allergic reaction, the temperature going up to 104° F. The blood count and differential count had remained unchanged. The drug was immediately discontinued. Therapy was then started again 10 days later with the same untoward response after the second dose, this time of only 50 mgm. per dosage. Thorazine was again discontinued. Though the patient had only 4 days of medication altogether, she became less tense and irritable, and up to date is able to maintain sufficient emotional balance to be able to function at home.

This study has, however, shown some more factors which seem to be too important

to be overlooked. The difficulties encountered by many of these patients after their release from the hospital are manifold and are frequently so severe that they are bound to eventually exert unbearable stress resulting in return of psychotic symptoms leading to the patient's return to the hospital.

CASE I.—Jerry B. comes from a broken home. He was 4 years old when his parents separated and was left with his mother. There were no siblings. When he was 8 years old his father, whom he only saw sporadically, remarried. Jerry was always jealous of the children of the second marriage of his father. His own mother had little understanding and patience with him. At the age of 10, he began to have difficulties at school, gradually became more and more aggressive and abusive to other children and at the age of 13 had to be hospitalized. From then on, he was almost continuously in the hospital until finally at the age of 19, after a course of chlorpromazine treatment, was released on convalescent care. He was continued on a maintenance dose and did quite well. He went to trade school and in spite of marked lack of self confidence came out as top of the class at the end of the school year. Throughout this year of convalescent care, his mother showed considerable ambivalence toward him, being one day unduly concerned, the next day openly rejective of him. While in school, he had been able to maintain his level of adjustment in spite of his mother's attitude. However, during vacation time, the difficulties between Jerry and his mother became more and more pronounced, until one day at the clinic he expressed the desire to be returned to the hospital. When questioned about his reason for this, he stated: "Don't you see, neither my mother nor my father cares about me. The hospital is the only real home I ever had." All attempts toward reassuring him were unsuccessful, as were all attempts to place him in a foster home. Two weeks later, the mother reported that Jerry had become very upset and she had had to return him to the hospital.

CASE II. A.S. who had been in the hospital for about 18 months, was released to the custody of her sons with whom she had lived prior to her hospitalization. On the way home from the hospital, the sons revealed to the mother for the first time that they had moved out of the apartment which the patient had occupied for over 30 years. Moreover, the older son had married and the mother was now faced with the situation of sharing the new apartment, in a completely new neighborhood, with a daughter-in-law, who was a complete stranger. Out of her old possessions, there was not one single item left. It is understandable that this patient became extremely upset and to this day, 6 months later, she still has not made a full adjustment. "I don't know a soul in the vicinity, I can't handle all these new gadgets they bought, I don't know, does the girl live with me or do I live with them?" It is felt that the only reason why return to the hospital was prevented so far is the fact that

she is seen regularly once a week and occasionally more often and supportive therapy is being offered. This, together with the Thorazine maintenance dosage which had to be adjusted several times according to needs, seems to have kept her out of the hospital up to date.

CASE III.—Mrs. C.M. had been hospitalized for over 4 years. In spite of the fact that her husband during the years of her absence had become an alcoholic, she not only adjusted well to life in the community, but even managed to get him to stop drinking, took complete control of her household, took active part in the parent-teacher organization of her sons school and lead again a normal social life. All went well for 8 months during which she was kept on a maintenance dose of 50 mgm. Thorazine daily. Three months ago, when visiting the clinic again, she was found to be tense and quite upset, looked drawn. When asked about the reason for this, she started to cry and gave the following tragic account:

Her 15-year-old son when running after another boy had fallen and injured his right knee. As the pain persisted he was taken to the family physician and in the course of examinations it was found that there was a malignant tumor of the femur. He was admitted to the hospital for observation and she had just received word that a high amputation would have to be performed and that even with this operation chances for his survival were rather poor. In response to this sad news her husband has started to drink again. Upon her own request she visited the clinic more frequently and her Thorazine dose is being adjusted from week to week. The boy, now after a high amputation of the right leg is still hospitalized and she visits him regularly every day. She has learned to face the situation and is even able to give her husband so much support that he can stay away from the alcohol. She is fully aware of the fact that her boy's days are counted. It is felt that both supportive therapy as well as the Thorazine have so far helped this woman to maintain her emotional balance and have prevented a relapse in this patient, who without this, undoubtedly and understandably would have broken down under the impact of a cruel fate.

In summarizing what has been observed so far, the study seems to indicate that there are far less untoward side effects caused by chlorpromazine even when taken for a prolonged period of time than might have been anticipated. But, it appears to be impera-

tive that these patients be seen regularly for proper control of dosage, not only in order to avoid unpleasant complications, but also to vary the dosage according to individual needs, taking into account the increased stress situations which have to be faced by these patients outside the hospital.

It seems that a single daily dosage given at bedtime (50-150 mgm. Thorazine) can in the majority of cases supply a sufficient amount for the maintenance of the level of improvement and, at the same time, keep the patient from suffering from drowsiness and other side effects which might interfere with work. This is important because of the 82 patients presently on maintenance dosage, 58 are working, 41 of them receiving a bedtime dosage only.

Patients who have had a long duration of illness always seem to require a maintenance dosage, as they do show, sooner or later, return of psychotic symptoms when the drug is discontinued.

Another important reason for seeing these patients in regular and frequent intervals is the need to determine whether or not the drug is actually being taken. It happened on various occasions that patients when coming to the clinic were noticed to be tense, irritable. Investigation frequently revealed that the drug had not been taken for several days. Stress situations requiring change of dosage can, too, be discovered in due time, only, if these patients are seen frequently enough.

Social factors should be kept in mind as they can eventually cause failure in the attempts toward readjustment of these patients. Then Thorazine, a most effective and valuable weapon in our fight against mental illness, could be discredited as ineffective where so frequently unfavorable social situations are actually to be blamed for these patients' return to the hospital.

RESULTS OF FOUR YEARS ACTIVE THERAPY FOR CHRONIC MENTAL PATIENTS AND THE VALUE OF AN INDIVIDUAL MAINTENANCE DOSE OF ECT

GUNTHER E. WOLFF, M.D.¹

More than 4 years have passed since we started a more active treatment for our geriatric female mental patients at the Camarillo State Hospital. The *systematic* use of ECT for this type of elderly patient has never been attempted before though some are on record who have received occasional ECT for acute emergencies.

It was our hope to relieve the condition of the most pitiful patients. Some were completely withdrawn, refused to eat, tried to commit suicide or in a most morbid way played with or ate their excrements. Others were destructive to themselves or their surroundings, tearing up their mattresses, banging the doors, screaming at the top of their voices or attacking patients and attendants if not heavily sedated or in restraint. Certainly this was a life so full of suffering and misery that it far surpassed any we had encountered in patients afflicted with cancer or other chronic organic illnesses.

ECT is a well established procedure in our armamentarium and we like to call it the "surgery" in psychiatry. In spite of this fact no treatment in any field of medicine has been so handicapped by sharp and unjustified criticism. This was never more evident than during the last 2 years when the pages of our medical journals have become crowded with articles concerning the tranquillizing drugs. Instead of waiting to ascertain that no side or after effects of these helpful drugs might develop, statements have been made again and again that these drugs will reduce or eliminate ECT. One article from a quite prominent author even went to the extent of saying "Electric shock is not only dreaded by patients, but also fails to show permanent therapeutic results except in depression" (is that nothing?). "Less dramatic and brutal than Electric Shock, insulin therapy also has only transitory effect on Schizophrenics." Notwithstanding this widely held opinion nothing

has convinced us more of the value of ECT in certain cases than our results during the last 4 years. We have been using every method to help our patients. Many have become more cooperative, relaxed and amenable to psychotherapy with tranquillizing drugs. However, quite a number could not maintain their improvement and others continued to be very disturbed, either depressed or hyperactive. They received ECT and the majority have shown improvement which no other therapy had accomplished.

Of 200 patients now on active treatment, 61 are receiving tranquillizing drugs only; 82 are on ECT only; and 57 are on ECT plus tranquillizing drugs.

We were fully aware that our work involved calculated risks such as complications from the cardiovascular system or occasional fractures. If these had materialized part of our purpose might have been defeated; however, none of these accidents occurred and our initial results were very impressive and encouraging. We wish to mention here that we might have been easily misled. During the initial period we had 2 patients approved by staff for ECT; one of them died from an acute coronary thrombosis the day she was approved and another the day after approval, from a cerebral hemorrhage before having received *any* treatment. If they had received even one treatment, who could have judged whether or not death was the result of ECT?

From the outset we *never* believed that the "death fear" or the "feeling of punishment" could be responsible for the good results of ECT, an opinion which unfortunately is still prevalent. We were very much impressed by the work of Funkenstein and his co-workers who since 1949 have proven that in many mental conditions, a disturbed homeostasis of the autonomic nervous system is present and that after successful electric convulsive treatment, homeostasis is re-established. In the last few years research has further brought out the fact that bio-

¹ Camarillo State Hospital, Camarillo, Cal.

chemical and physiological changes in the brain tissues of mentally disturbed patients are responsible for their illness, and that these changes are often reversible. We older physicians still remember our utter ignorance of the cause of diabetes or pernicious anemia until the discovery of insulin and the liver enzyme changed the whole aspect of these often deadly diseases. Is it not possible that we are standing at the threshold of a similar development for mental illness? It only seems that the clinicians are still very reluctant to recognize and follow the genius of research, a fact not unknown in medicine.

From August 1952 until September 1956 we have been treating 505 patients with ECT; of these about 350 are elderly, mostly bed ridden patients more or less in need of general care. However, a few of them are so mentally disturbed and upsetting to the others that in spite of their advanced age, they have been receiving ECT for more than 3 years and without any exception have greatly benefited from it.

The histories of a few typical cases follow:

19620—C.P.: This patient was committed on August 30, 1948, and diagnosed chronic brain syndrome associated with cerebral arteriosclerosis with psychotic reaction. She was a very frail person refusing food, combative and resistive so that she had to be frequently in restraint or seclusion. She responded very well to a few ECT, went on convalescent leave from February to June 1949 and was returned because of a complete relapse. She responded well again to 14 ECT and went on another convalescent leave from October to December 1949. These ups and downs continued. However, she is now on a maintenance dose of ECT, about 2 treatments every 3 weeks, which avoids any relapse. She is pleasant, cooperative, in very good contact and has a good insight. She has received altogether 242 ECT. Her present age is 82.

34476—S.A.: This patient was committed on March 3, 1953, and diagnosed chronic brain syndrome with senile brain disease with psychotic reaction. She was very agitated, destructive, combative, belligerent and noisy. She improved on ECT. It is necessary to keep her on a maintenance dose of one treatment a week and in this way she is friendly, cooperative and even cheerful. She has had 142 treatments. Her present age is 88.

28846—H.E.: This patient was committed on October 9, 1951, and diagnosed chronic brain syndrome with senile brain disease with psychotic reaction. She was depressed, not eating and so feeble that the admission physician wrote "no ECT." She was also very combative and noisy at the same time. She was physically and mentally deteriorat-

ing and staff finally approved ECT. She improved after a series of 14 ECT and is holding well with 1 treatment every 2 weeks. Altogether she had 119 treatments. Her age is 83.

32941—D.M.: This patient was committed on October 23, 1952, and diagnosed chronic brain syndrome with senile brain disease with psychotic reaction. She was very depressed, refused to eat and became bed ridden. A series of ECT improved her very much and now she is on one treatment a week, able to sit up, eating well and in fair contact. Her age is 90.

The establishment of a "maintenance dose" of ECT for most of our patients has helped us to make them comfortable and not only add "years to life" but "life to years."

The patients were diagnosed as:

Chronic brain syndrome with cerebral arteriosclerosis or senile brain disease with psychotic reaction	200
Involuntal psychotic reaction	91
Schizophrenic reaction, various types	94
Manic-depressive reaction, manic or depressed type	36
Chronic brain syndrome associated with diseases of unknown or uncertain cause (Pick's and Alzheimer's Disease)	5
Chronic brain syndrome associated with convulsive disorder with psychotic reaction..	24
Psychoneurotic reactions, various types	12
Chronic brain syndrome associated with disturbance of metabolism, growth or nutrition with psychotic reaction.....	8
Chronic brain syndrome associated with alcohol intoxication with psychotic reaction	18
Chronic brain syndrome associated with central nervous system syphilis with psychotic reaction	4
Chronic brain syndrome, multiple sclerosis with psychotic reaction	6
Chronic brain syndrome with intracranial neoplasm with psychotic reaction.....	3
Mental deficiency with psychotic reaction	4
	505

The age distribution of our patients will be shown by the following table:

Under 50	50-60	60-70	70-80	80-90	Over 90	Total
57	126	190	75	51	4	505

These patients were selected from the following types of wards:

- I The most disturbed with a population of 100
- II A chronic senile ward with 111 ambulatory patients
- III A chronic senile ward with 121 patients who had to be fed on the ward because they were too feeble to go to the dining room. (Actually old people who needed general care.)
- IV Two senile bed wards with a population of 180

V An infirmary ward with about 100 elderly patients suffering from one or another organic disease.

Before we started this form of therapy we had daily to give on Ward I sedation by hypo to about 15 patients, we had to feed by spoon or tube about 20 and to keep in seclusion or restraint 8 to 10. Now all patients are able to go to the dining room; we give monthly only 2 to 3 sedations by hypo, mostly to patients who are newly admitted. There are none in seclusion or restraint. The whole atmosphere on this ward has so changed that the attendants are now able to spend their time discussing the patients' problems with them instead of being constantly on the alert against fights or destructiveness. By eliminating the very disturbing elements by means of this therapy, it has helped to improve the condition of many other patients. Many of the medical and nursing staff of this hospital have remarked about the complete change in the behavior and attitude on this once very disturbed ward.

Since August 1952 we have been able to send on convalescent leave from the Very Disturbed Ward I, 56 patients; 41 of whom had EST. Ward II, 103 patients; 46 of whom have had EST.

We feel we can be proud of this accomplishment which compares favorably with the results of active treatment wards. We were actually dealing with chronic "custodial" patients who previously were only rarely able to go on convalescent leave. This was not a "pilot study," but accomplished with the not very numerous personnel on this type of ward. We have treated to date almost 700 patients with more than 22,000 ECT. We were fortunate to have no cardiovascular or other serious complications in spite of the advanced age of most of our patients. We had about 25 fractured bones (vertebrae, hip, pelvis and forearm, in this order). During the same period on the same service we had over 178 fractures due to falls and other reasons.

Let me emphasize that in ECT as in any other form of therapy the attitude of the whole nursing staff and the physician is of utmost importance. They all must have confidence and be optimistic about this treatment and by their attitude transmit this feeling to

our patients. None of our attendants are allowed to convey the slightest impression that this treatment is a kind of punishment, or dare to threaten a patient with it. No patient is ever surprised with ECT. They are always told in advance, even if they are very disturbed, that this electric treatment will help them. Only a few remain resistive, and these actually are those who refuse any medication or fight injections with all their strength. Those who were apprehensive were sedated in the beginning until they lost their fear after realizing that we were helping them. Only 2 continue to require sedation before each session. We wish to emphasize that ECT should be given by the physician in charge of the patient and not by a special ECT team who can have only very little knowledge and contact with each individual. The close observation of our patients and the favorable results of our active therapy have intensified in us the feeling, well supported by the latest research, that ECT must produce a biochemical or other form of metabolic change in the brain. From my experience of 25 years in internal medicine, I have learned that some diseases will never be cured permanently and that certain patients are able to carry on only by getting a maintenance dose of their medication whether this is digitalis for the chronic cardiac, insulin for the diabetic or B-12 for the pernicious anemic. No doctor would ever dream of discontinuing an established maintenance dose because he would know that he might endanger the health or even the life of his patient. We felt that a similar consideration should be applied to ECT. From the moment that this idea capitivated us, we have tried to find for each of our patients her maintenance dose by closely watching her mental pattern. After a level of improvement is maintained we never wait for a complete relapse, but give the next treatment the moment we observe the slightest regression. Some patients need their treatment weekly, some every 2 weeks, some in monthly or longer intervals. In this way we have been able to maintain the improved atmosphere on the whole ward as mentioned before. The correctness of these observations is substantiated by the facts that:

a. When these established maintenance

doses were discontinued while the routine ward doctor was away, the disturbing elements broke through again.

b. Quite a number of patients who are out on convalescent leave and receive their established maintenance dose of ECT have now been out for more than 18 months; previously, they had to be returned to the hospital every 3 or 4 months because of a relapse.

SUMMARY

This paper reports:

a. The results of 4 years active therapy on custodial wards with geriatric female patients.

b. The benefit and limitation of tranquilizing drugs.

c. The value of ECT as "surgery" in psychiatry.

d. The importance of establishing a maintenance dose of ECT for each individual patient.

PSYCHOPHYSIOLOGICAL GASTROINTESTINAL REACTIONS

VINCENT EDWARD LASCARA, M.D.¹

Before discussing psychosomatic gastrointestinal symptoms, a review of the nerve innervation of the gastrointestinal tract is desirable, so that we may have a better understanding of psychosomatic G.I. symptoms.

The esophagus and stomach are supplied by the right and left vagus nerves. The liver is innervated by the left vagus. The small intestine is supplied by the vagi and the sympathetic nerves. The large intestine receives its nerve supply from the sympathetic. The pancreas is also supplied by the sympathetic nerves. The descending colon and rectum are supplied by the pelvic plexuses. The abdominal viscera receive both sensory and motor branches from the thoracolumbar division of the sympathetic and the sacral division of the parasympathetic.

There are a number of sympathetic ganglia and plexuses. Some of the plexuses are paired, namely: phrenic, suprarenal, renal; also the spermatic in the male and the ovarian in the female. Unpaired plexuses are the aortic, hepatic, splenic, superior gastric (coronary), inferior gastric, superior mesenteric and inferior mesenteric. There are several sympathetic ganglia in the abdominal cavity, largest of these are the celiacs. The lumbar ganglia are composed of 3 to 8 pairs, usually 4. Four small sacral ganglia are usually found. From this review, it is apparent why we can have various dysfunctions in the abdominal area.

The abdomen is usually known as the sounding board of the emotions. We find frequent psychophysiological reactions in the gastrointestinal tract. Not only functional disorders, but also gross organic lesions can be caused by emotional stimuli. The most prevalent functional disorders include anorexia nervosa, nervous vomiting, constipation, nervous diarrhea, nervous indigestion, irritable colon, belching, epigastric distress, "butterflies" moving inside, flatulence from fright or hurt. The disturbances of function may lead to organic lesions such as

peptic ulcer and ulcerative colitis. A difficult environment may precipitate the organic lesions. Removal to a more wholesome environment may lead to a striking improvement. The total organism may need treatment. The esophagus and colon are proximal to branches of the central division of the nervous system and are more vulnerable to the emotions.

We must remember that G.I. complaints are encountered in many neurotic and functional reactions. They are encountered in the depressed phase of manic-depressive reaction and in schizophrenic reactions. Many patients have experienced sudden cessation of nausea and vomiting once they are removed from the noxious environment or situation. Unconscious mental conflicts can cause vomiting, the patient literally cannot "stomach" the situation. It is a physical manifestation of an escape mechanism. Vomiting of bile-stained fluid may indicate abdominal migraine. We should inquire if the patient suffers from migraine headaches. Nervous diarrhea, nervous colitis, spastic colon and irritable colon are looked upon as different manifestations of the same condition. The colon is sensitive to emotions and nervous tension. Family jealousy, parental domination, marital conflicts, family insecurity, morbid fears, frustrations, business reverses, family quarrels, sudden shocking news, identification with illness or death of a member of the family or a close friend, may, by suggestion, cause functional suffering in a predisposed individual.

Gastrointestinal functional complaints are usually of long duration with much detail, related to stress, and pain tends to shift. Once the patient goes to sleep, it is uncommon to be awakened by pain: an important differential point in relation to organic pain.

Anorexia nervosa represents punishment of self or others. Attempts to gain affection may be a motive. On the other hand, martyr complex or deep seated death wishes may lead to the anorexia. Figuratively, the stomach being moronic cannot distinguish be-

¹ Address: 1200 17th St., Newport News, Va.

tween hunger for food and hunger for affection.

Cardiospasm is considered to be more than a neurosis. The nerve plexuses at the cardia may be diseased. In many cases, dilatations will relieve the symptoms. Anthral spasms may be precipitated by emotional reactions.

Peptic ulcer is an organic disorder with close relationship to the emotions. Prolonged frustrations, suppressed emotions, may aid in ulcer formation. Constant bombardment of the nervous system by the emotions may increase the reaction of hyperacidity in ulcer formation. The ulcer patient is usually rigid, a chronic worrier, overconscientious, and aims at perfectionism. For best results, diet, chemotherapy and psychosomatic measures are necessary. A patient must learn to live with the ulcer and also how to live with it.

In nervous colitis, there is no colitis inflammation of the colon. There is sensitivity to stress, anxiety and tension. A psychic strain may lead to sudden "cramps," desire to have a stool with only passage of flatus, foam and a small amount of fluid.

Ulcerative colitis is another serious disorder in which the psychiatric complaint in the etiology is preponderant. Psychic factors cannot produce actual ulcers of the "bowel." A personality study is helpful towards treatment, usually emotional conflicts exist. Besides antibiotics, sulfonamides, and at times, cortisone, management and guidance of situational reactions is essential for the best results. The colon must be removed from irritating personal problems so that it can be peaceful from these irritating factors. It

can then take care of its bacterial invaders and amelioration will be evident.

In the diagnosis and treatment of psychophysiological reactions, we must rely on:

1. A good history by systems, past history, and family and personal history. A Cornell Index questionnaire is very helpful.
2. Careful laboratory studies are essential, including X-rays, blood studies, stool research, and various metabolic evaluations. Allergic studies may be necessary.
3. A complete physical and neurological examination.
4. Psychological studies are usually helpful in evaluating personality factors.
5. Psychiatric interviews are essential.
6. Special diets are usually indicated, chemotherapy in the form of sedatives, antispasmodics, and tranquilizing drugs.
7. In severe cases, shock therapy may be indicated as an aid towards improvement.
8. Telling the patients the illness is in their mind and that they will have to get over it themselves, leaves a bad taste. These persons are ill. They need support and aid towards solving their problems, and must receive interested attention.

CLINICAL NOTES

A PRELIMINARY REPORT ON MARSILID

FRANK J. AYD, JR., M. D.¹

Recently Marsilid (iproniazid) has been heralded as a new "psychic energizer" which elevates mood, stimulates appetite, increases weight, and restores vitality. Because of these effects Marsilid is recommended for treating mild depressions in ambulatory, non-psychotic patients and for stimulating appetite and promoting weight gain in debilitated patients. It is also suggested for hospitalized psychotics with severe depression or regressions.

Marsilid was prescribed for 14 men and 36 women (ages 22-70) who were diagnostically categorized: psychoneurosis—depressive reaction 12, hypochondriacal reaction 2, asthenic reaction 3, manic-depressive reactions—depressed 16, involutional depression 10, and schizophrenic reaction 7. Their essential complaints were weakness, lack of energy, easy fatigability, loss of interest, and feelings of dejection, insomnia, anorexia and weight loss. All patients were ambulatory.

Marsilid was administered without comment as to what it was, or the expected clinical response. Ten patients were given the drug in addition to other medication, 12 were started on an inert placebo followed by Marsilid, 15 received Marsilid alone, 13 were given Marsilid plus 5 mg. of d-amphetamine.

The usual dose for severely depressed and debilitated patients was 50 mg. 2 or 3 times daily. Mild and moderately ill patients were given 25 mg. 2 or 3 times a day. Except for those intolerant of Marsilid or who refused to take it because of side effects, all patients received the drug for more than 3 months.

Because Marsilid is a slow-acting drug,

therapeutic response did not occur before the third week of treatment. However, side effects were noted shortly after the institution of therapy. The drug had to be discontinued because some patients developed anxiety over autonomic side effects, severe postural hypotension, paranoid reaction with excitement, hypomanic psychosis, severe dyspnea, cardiac failure and enhanced depression. Common side effects were dryness of the mouth, blurred vision, constipation, delayed micturition, paresthesias and dizziness. Other patients had hyperreflexia, neuralgic pains, weakness and fatigue, itching, sweating, diarrhea, drowsiness, insomnia, and were sexually impotent. There was no positive correlation between dosage, duration of Marsilid therapy and the occurrence of side reactions. Some patients were able to tolerate 150 mg. daily, while others had serious reactions on 50 mg. a day.

The results obtained in the 39 patients who received Marsilid for 3 months were assayed by the following criteria: (1) improvement: almost complete symptomatic remission from depression and/or debilitation and (2) partial improvement: sufficient symptomatic relief to permit the patient to function more efficiently. By these standards 5 were improved, 19 partially improved, 15 were unimproved. If the 15 unimproved are combined with the 11 patients who had to be dropped because of side-effects then over half of the original patients started on Marsilid did not benefit from this drug.

Psychotherapy was an essential for patients treated with Marsilid. This drug is not always a psychic energizer. It may be a tranquilizer or a psychotomimetic drug. Although potentially useful, it should be prescribed cautiously for ambulatory patients who can be carefully supervised.

¹ Chief of Psychiatry, Franklin Square Hospital, Baltimore, Md.

TREATMENT OF PSYCHOSES WITH A COMBINATION OF PACATAL AND THORAZINE¹

MANFRED BRAUN, M.D.²

The rationale for using a combination of Pacatal and Thorazine, in the treatment of psychoses, was suggested by Hiob and Hippus(1) and by Bowes(2). The former demonstrated that the combination proved highly beneficial in treating patients who were resistant to ECT or resistant to therapy with one of the drugs alone. Furthermore, the smaller dosages employed decreased some of the common side effects. Bowes pointed out that the more pronounced parasympatholytic action of Pacatal is balanced by the more pronounced sympatholytic action of Thorazine. Moreover, Pacatal was found to be mildly euphoriant, whereas Thorazine was more sedating.

Our preliminary clinical trials with this Pacatal-Thorazine combination revealed that the outward behavior manifested by these patients offered a practical guide for estimating the initial dosage ratio employed. Therefore, we classified the 42 schizophrenics in this series into 2 categories. Group I contained 20 patients whose behavior was characteristically overactive and agitated. In contrast, the behavior of 22 patients in Group II was characteristically lethargic, withdrawn and asocial.

Taking advantage of the sedating action of Thorazine, the patients in Group I were started on a combination of Pacatal, 50 mg. b.i.d., and Thorazine, 50 mg. q.i.d. Many were adequately controlled at this dosage level. In those instances where additional sedation was required, the dosage of Thorazine was increased to 100 mg. q.i.d. and the Pacatal dosage remained at 50 mg. b.i.d. Whatever adjustments in dosage were made, the final dosage was gradually reduced to a

maintenance dose of Pacatal, 50 mg. b.i.d., and Thorazine, 50 mg. q.i.d.

Utilizing the euphoriant effect of Pacatal, patients in Group II were given Pacatal, 50 mg. q.i.d., and Thorazine, 50 mg. b.i.d. Individual patient requirements necessitated dosage changes but the maintenance dose arrived at for most patients in Group II was Pacatal, 50 mg. b.i.d., and Thorazine, 50 mg. b.i.d.

Eighty-eight per cent of the 42 patients, all of whom were schizophrenics and refractory to all other medications, demonstrated a considerable improvement. No side effects were observed and all blood studies were found to be negative. Blood pressures remained normal. A typical case history illustrates the response obtained by most patients.

Seventeen year old female. Catatonic schizophrenic with episodes of excitation and stupor. She had been hospitalized for past 2 years and during this period received all indicated therapy, including ataractic agents, without responding in a satisfactory manner. Pacatal, 50 mg. b.i.d., plus Thorazine, 50 mg. q.i.d., was then substituted for all other medication. This initial dosage was changed after a few days to Pacatal, 100 mg. b.i.d., and Thorazine, 100 mg. q.i.d. Within a few days a favorable response was noted and the dosage was gradually reduced to Pacatal, 50 mg. q.i.d., and Thorazine, 100 mg. q.i.d. The degree and type of improvement was remarkable. The prompt disappearance of the frequent episodes of excitation and stupor, characteristic of her previous behavior, represented a basic change. She spontaneously asked ward attendants to provide work and some activity. This obvious improvement in affect had never occurred before. She has now been participating in group activity for over 3 months and her outlook is good.

THE USE OF HEXAFLUORODIETHYL ETHER (INDOKLON) AS AN INHALANT CONVULSANT

AUGUSTO ESQUIBEL,¹ JOHN C. KRANTZ, JR.,² EDWARD B. TRUITT,³ AND
ALBERT A. KURLAND⁴

Although hexafluorodiethyl ether ($\text{CF}_3\text{CH}_2\text{OCH}_2\text{CF}_3$) was originally synthesized for the purpose of determining whether it possessed anesthetic properties, it was found that the inhalation of its vapors produced convulsive seizures in many species of laboratory animals.

This drug is now being investigated concerning its usefulness as a convulsant in the treatment of hospitalized psychiatric patients. To date a total of 434 treatments have been administered to a group of 40 patients. The only complication so far observed has been a compression fracture of a thoracic vertebra. Routine laboratory studies of blood, urine, and liver function as well as EKG studies have disclosed no abnormalities.

The procedure for administering the drug is through the use of a Stephenson mask modified appropriately with one way valve to which the Indoklon vaporizer can be attached and the exhaled vapor absorbed by an activated charcoal exhalant (1). The dosage used varies according to the individual but remains within the range of 0.3 cc. to 1.5 cc. Treatments were given three times a week, and each patient received, on the average, 12 treatments.

The time required to induce convulsions varies with each individual treatment, but has averaged about 30 seconds. The seizure begins with a few premonitory myoclonic jerks which are followed by the onset of a tonic phase without the marked "jack-knif-

ing" effect so characteristic of the onset of electroconvulsive therapy. There also seems to be less apnea associated with this treatment than with electroconvulsive therapy, and less confusion and psychomotor activity in the immediate post-convulsive period.

Subjectively, a great many of the patients who have experienced this procedure and who have had electroconvulsive therapy in the past, while not feeling enthusiastic about either treatment seem to feel less threatened by the convulsive inhalant. In those patients who have developed an intense apprehension to electroconvulsive therapy, this offers an alternate choice which is more acceptable to the patient. Whether this type of treatment brings about the degree of post-convulsive amnesia and confusion as that produced by electroconvulsive therapy is being investigated by means of psychological studies but as yet sufficient data are not available to make any statements.

ACKNOWLEDGMENTS

This research was made possible by a grant from the Ohio Chemical and Surgical Equipment Company and the support of Friends of Psychiatric Research, Inc. With great appreciation acknowledgment is made of the administrative and clinical support by Dr. Isadore Tuerk, Superintendent, and Dr. Charles Ward, Clinical Director, Spring Grove State Hospital.

CASE REPORTS

A CASE OF AGRANULOCYTOSIS FOLLOWING "SPARINE" ADMINISTRATION

MELVIN J. REINHART, M.D.,¹ BERNARD S. SILVERSTEIN, M.D.,² AND
THOMAS N. CROSS, M.D.¹

Since few cases of agranulocytosis have been noted following Sparine administration, it seemed wise to us to report the following case.

M. S., a 49-year-old male, was admitted to the Neuropsychiatric Institute May 25, 1957. A diagnosis of schizophrenic reaction, undifferentiated type, chronic, was made at the time of admission. In 1949 and 1955 a similar diagnosis was made on admission to a state hospital. He received electroconvulsive therapy on both occasions. Following the ECT in 1955, the patient was placed on Thorazine beginning with a dosage of 25 mg. t.i.d. which was increased to 100 mg. t.i.d. 4 days later. After about a month he developed clay-colored stools, icteric sclerae, low-grade temperature, and a generalized pruritis. His serum bilirubin was 4.5. Urinalysis showed a trace of albumen and a positive test for bile pigment. The hemoglobin was 16.6 grams and the white blood cell count was 6,650 with a normal differential (polymorphonuclears 70%, lymphocytes 23%, monocytes 6%, basophils 1%). The thymol turbidity was 1.6 units. According to history, the patient's symptomatology cleared spontaneously following the withdrawal of the drug.

On admission to the Neuropsychiatric Institute, 2 years later, the patient was placed on 50 mg. of Sparine q.i.d. The next day the dosage was increased to 100 mg. q.i.d. and 2 days after admission Ritalin, 10 mg. t.i.d. was added to combat an increasing depression. Sparine and Ritalin were continued at these dosages for 6 days, until June 4, when because of progressive agitation the Ritalin was discontinued and the Sparine

was increased to 250 mg. q.i.d. Because of increasing lethargy the Sparine was decreased to 150 mg. q.i.d. on June 10.

The admission physical examination revealed no abnormalities. As there was a history of subtotal thyroidectomy in 1942, thyroid studies were initiated May 29. A BMR was plus 22% and serum cholesterol 126 mg. %. Hemoglobin was 14.9 grams or 95% and the white blood cell count was 5,700. Urinalysis and chest film were negative.

Because of pitting edema of the lower extremities, exertional dyspnea, and increasing fatigue the patient was felt by the medical consultant on June 10 to have arteriosclerotic heart disease with hyperthyroidism. Digitalis and thimerin were administered on June 11. The next day a PBI was reported as 11.3 gamma % with inorganic iodine 1.8 gamma %. His temperature on June 12 was 102.6° orally with a pulse rate of 120. An electrocardiogram revealed only sinus tachycardia. It was felt by the consultant that the diagnosis at that time was "thyrotoxicosis with a question of borderline thyroid storm."

A CBC done at the time of transfer to internal medicine June 12 revealed a white blood cell count of 2,700 with a differential of 90% lymphocytes and 10% monocytes—no granulocytes were seen. Although Sparine was immediately discontinued, the patient's temperature rose to 104° rectally, occasionally spiking to 105.6°. The febrile course continued despite massive doses of antibiotics.

On June 13 the total serum bilirubin was 2.3 mg. % with a BSP retention of 38%. With a progressive jaundice the white blood cell count dropped to 550 on June 20.

A bone marrow examination June 13 revealed "megakaryocytes are present in normal numbers forming platelets. There is no

¹From the Neuropsychiatric Institute, Ann Arbor, Michigan.

²From the Department of Internal Medicine, University Hospital, Ann Arbor, Michigan.

evidence of granulopoiesis. Erythropoiesis is normoblastic with some cells showing rather clumped chromatin patterns. Plasma cells are numerous, most mature in appearance but some show nucleoli and have light blue vacuolated cytoplasm. An occasional reticulum cell is seen. Mast cells are not seen."³ This was interpreted to represent a more severe bone marrow damage than the maturational arrest usually seen in agranulocytosis.

On June 22 the temperature dropped to normal levels and remained there for several days. The white blood cell count on June 25 was 22,600 with 82% granulocytes on differential (blastocytes 1%, progranulocytes 6%, myelocytes 7%, metamyelocytes 8%, bands 22%, segs 38%). His physical condition improved markedly. The jaundice

cleared entirely by June 28. Subsequently the patient encountered complications including a septicemia and a bronchopleural fistula and at the time of this writing is on the critical list.

This is the only case of agranulocytosis following Sparine administration observed at our institute. Unlike the few previously reported cases there was a lapse of 12 days following the discovery of agranulocytosis before evidence of granulopoiesis was noted.

In view of this experience and the reports of hematologic evidences of toxicity with other phenothiazine derivatives we have begun a program of weekly WBC for one month on all patients starting on these drugs. The following month fortnightly checks are made. It is also essential to carefully evaluate the symptomatology of all patients on these drugs in order to detect early evidence of toxicity since the WBC can change precipitously from day to day.

"PARADOXICAL" EFFECT OF CHLORPROMAZINE IN A CASE OF PERIODIC CATATONIA

WALTER KRUSE, M.D.²

A small number of schizophrenic patients, when placed on chlorpromazine, show increasing restlessness, agitation, and outbursts of aggressive behavior. This is not a transitory effect comparable to the "turbulent phase" in reserpine patients but it continues as long as chlorpromazine is given. A similar "paradoxical" effect was observed in the following case of periodic catatonia.

Our patient is a 50 year old white male whose mental illness began when he was 30. He was restless, excited and had auditory hallucinations. He made a fair recovery, but 6 years later he became ill again, and since then he has suffered periodic psychotic episodes, always characterized by excitement, extreme psychomotor activity, personality disintegration, disordered thinking, auditory hallucinations and delusional ideas. The phases of excitement began with the appearance of tension, restlessness, abnormal irritability, flushing of the face, and insomnia. At the end of each phase he would sleep for 1 or 2 days. During the "free"

interval he was able to work in the hospital and did not show any gross psychotic symptoms. From 1953 to 1955 exact records were kept, and the total of excited periods amounted to 32% while the "free" intervals were 68%. The duration of excited phases was most often 2 to 3 weeks, that of the "free" intervals usually between 3 and 6 weeks.

In November, 1955, he received a combined medication of up to 400 mg. chlorpromazine plus 4 mg. reserpine daily, for the following 6 months chlorpromazine only. The average daily dose was 150 mg. i.m. or 300 mg. p.o. During this period of treatment our patient's condition deteriorated markedly. The excited phases became longer and followed upon each other in rapid succession. They reached a degree of utmost severity. There were only 104 days of "free" interval and 115 days of excitement. (Following this 7 month period chlorpromazine was discontinued and Ext. Thyroid was given with immediate beneficial results.)

In trying to explain the "paradoxical" effect of chlorpromazine, Selbach's "principle of the regulatory circle"⁽¹⁾ has proved helpful. Autonomic centers in the diencephalon seem to play the central role in the periodic changes of this rare type of catatonia. A shift in the balance existing between the centers of the ergotropic (sym-

¹ This study was made at the Vermont State Hospital. I should like to express my gratitude to Dr. R. A. Chittick, Superintendent of the Vermont State Hospital, for his helpful suggestions.

² Address: Box 50, Hathorne, Mass.

pathetico-adrenal) and trophotropic (vago-insulin) systems is accompanied by a change in the clinical picture. Gjessing and other workers in this field agree that in the "free" interval there is a shift in the balance toward the trophotropic side. The phase of excitement, according to Selbach's principle, would then represent a secondary compensatory ergotropic reaction, an adjustment mechanism to counteract the maximal trophotropy. At the end of the excited period there is a lytic return to the equilibrium via the sleep phase. In considering the essentially trophotropic action of chlorpromazine, the "paradoxical" effect in our patient seems not surprising.

Chlorpromazine medication during the "free" interval led to an increased trophotropy in our already trophotropic patient and aggravated the existing disturbance of the autonomic centers. The maximum trophotropy was reached in a shorter time, thus reducing the "free" interval. The resulting compensatory ergotropic adjustment reaction (excited phase) could then be expected to be of a more severe nature.

AGRANULOCYTOSIS DURING TREATMENT WITH METHYLPROMAZINE¹

PAUL E. FELDMAN, M.D. AND JEROME STATMAN, M.D.²

Reports of agranulocytosis as a complication of phenothiazine therapy are appearing with increasing frequency. A review of the current literature indicates that this untoward effect of therapy may be more common than the often quoted incidence of 1:50,000-100,000(1). It is impracticable with the available data to attempt to estimate the number of cases of agranulocytosis which may have occurred. Individual reports have listed an incidence as high as 1:700(2) or 1:400(3). Pollack(4) in his review of the literature quotes an incidence as high as 1:150.

Pooling all data, it appears that the average patient who develops agranulocytosis during the course of phenothiazine therapy may be a female in her late 50's who has been treated for approximately 6 weeks prior to the onset of symptoms. Her chances of surviving this complication are 2 out of 3.

The medical regime for the management of agranulocytosis has been fairly well standardized, and with minor exceptions, is the same throughout the country. It consists of:

1. Immediate cessation of phenothiazine therapy.

2. Massive doses of antibiotics.

3. Non-specific supportive measures (pentonucleotides, parenteral fluids and liver extracts).

4. Symptomatic medication.

The use of steroids is of questionable benefit. Although agranulocytosis is thought to be an allergic phenomenon and steroids are known to stimulate the release of neutrophils if the precursors are present in the bone marrow, steroids suppress the connective tissue reaction and this is of great importance when there is an absence of granulocytes. The transfusion of whole blood has been accompanied by a higher than average mortality and this treatment has therefore fallen into disfavor.

The following case is reported not because the incidence, treatment or symptomatology was unique but because this is the first reported case of agranulocytosis occurring during treatment with a new phenothiazine compound.

Case Report.—Seventy-seven-year-old, white male. **Diagnosis.**—Chronic brain syndrome associated with cerebral arteriosclerosis with mild congestive failure secondary to arteriosclerotic heart disease. Routine laboratory studies were within normal limits.

Shortly after admission, treatment was started with Methylpromazine, 25 mgm t.i.d. and 25 days later the dosage was increased to 50 mgm t.i.d. On the 45th day the dosage was again increased to 75

¹ 10-(3 dimethylaminopropyl)-2-methyl phenothiazine hydrochloride.

² Topeka State Hospital, Topeka, Kansas.

mgm t.i.d. On the 51st day of treatment the patient appeared ill, temperature 101.6 (R) and had slight pharyngeal injection and gingivitis. X-ray revealed minimal bronchopneumonia in the left base and a throat swab grew alpha streptococci (viridans). W.B.C. was 2,800 with 1% eosinophiles and 99% lymphocytes.

Methylpromazine was discontinued and patient was placed upon a treatment regime which included 1,600,000 units of penicillin and one ampule of Combiotic daily. This regime was continued for 14 days. On the 3rd day the W.B.C. was 950 with 100% lymphocytes following which there occurred a gradual and progressive increase so that by the 15th day the W.B.C. was 6,500 with 74% segs, 25% lymphocytes and 1% monocytes. Recovery was uneventful.

In keeping with the policy (5) of considering all fevers of undetermined origin as possible cases of agranulocytosis until proven otherwise (when they occur during

the course of phenothiazine therapy), an early diagnosis of agranulocytosis and a favorable result from treatment was possible.

EQUITY

I have no special regard for Satan, but I can at least claim that I have no prejudice against him. It may even be that I have been a little in his favor, on account of his not having a fair show. All religions issue Bibles against him, but we never hear his side. We have none but the evidence for the prosecution, and yet we have rendered the verdict. To my mind this is irregular. It is un-English, it is un-American.

Of course, Satan has some kind of a case, it goes without saying. It may be a poor one, but that is nothing; that can be said about any of us. As soon as I can get at the facts I will undertake his rehabilitation myself, if I can find an impolite publisher. It is a thing which we ought to do for anybody who is under a cloud.

We may not pay him reverence, for that would be indiscreet, but we can at least respect his talents. A person who has for untold centuries maintained the imposing position of spiritual head of four-fifths of the human race, and political head of the whole of it, must be granted the possession of executive abilities of the loftiest order. In his large presence the other popes and politicians shrink to midgets for the microscope. I would like to see him. I would rather see him and shake him by the tail than any other member of the European Concert.

—MARK TWAIN

COMMENT

ON THE OCCASION OF ERWIN STRANSKY'S 80TH BIRTHDAY

Erwin Stransky was born in Vienna on July 3, 1877, and received the degree of Doctor of Medicine from that city's university in 1900. The following year he joined the First Psychiatric Clinic in Vienna under Wagner-Jauregg and worked there as clinical assistant for 7 years. Thereafter he gave up his position but remained in close contact with the clinic as "Alter Herr." In 1906 he was appointed to the permanent position of expert consultant in psychiatry and neurology to the court of law in Vienna. He became "Privat-Dozent" in 1908, was appointed director of a workers' insurance clinic in 1911, and associate professor of psychiatry and neurology at the University of Vienna in 1915. His teacher, Wagner-Jauregg, suggested his appointment to full professorship 4 times, but the political situation in Austria interfered. Stransky was forced into temporary retirement for 7 years. In May, 1945 Stransky was made director of the Municipal Institute for Nervous Diseases, Rosenhügel, because he had reached the age of retirement.

It is difficult to describe Stransky's work completely. It comprised nearly all fields of psychiatry, neurology, medical psychology, psychotherapy and mental hygiene. Stransky published 257 scientific papers among them 13 monographs, some of which were textbooks and articles in handbooks. His first papers were rather of experimental histological and neurological nature. He described several staining methods, published several papers on discontinuous degeneration in peripheral nerves and an original paper on associated nystagmus. Later, his neurological papers dealt with the diseases of the peripheral nerves, particularly neuritis to which his attention had been drawn by his experiences in the military service during World War I. Shortly before World War II, Stransky introduced a new treatment for multiple sclerosis, namely heterohemotherapy (*Fremdblutbehandlung*) which since has found general recognition. He described his own experi-

ences with this form of treatment in 11 papers.

Stransky first began to concern himself with the problem of schizophrenia, at that time still called *dementia praecox*, in the paper he wrote on the occasion of his appointment as "Privat-Dozent," and he never disassociated himself from this field of research which was of special interest to him. In this paper he pointed to the disassociation of the thymopsyche from the noopsyche as the essential characteristic of the schizophrenic disorder. He called this disassociation "intrap-sychic ataxia," and ably defended his view on the schizophrenic process against such authorities as Bleuler and Kraepelin. It may be mentioned that in 1932 Stransky described the case of a catatonic patient who suffered a fatal accident by an electric current. The patient showed a temporary remission of his psychosis before his death and Stransky saw in this fact an indication for a possible therapy of schizophrenia, thus anticipating electroshock treatment.

Stransky published 6 papers, some of which were monographs, on manic-depressive psychosis and 15 on problems of forensic psychiatry and in these papers introduced the concept of the "initial offense." Throughout his whole scientific life Stransky has been very interested in all problems of mental hygiene, psychotherapy and neurosis, frequently expressing views quite different from those of Freud. Fifty-seven papers, some of them monographs, contain his ideas and experiences in this field. He was the first to publish a textbook on mental health in German and he became an ardent protagonist of this movement in Austria. The inauguration of applied psychopathology is also to his merit.

In 1945, after 7 years of humiliation, Stransky was able to resume his work in and for the public. He did not miss any scientific meeting or convention in the broad field of neurology and psychiatry, attending many conventions abroad, frequently as of-

ficial representative of Austria, whose interests he upheld as a scientist and a dignified human being. Stransky is the only Austrian who is an Honorary Member of The American Psychiatric Association. He is also honorary president of a number of scientific societies in Austria, and honorary or corresponding member of various scientific associations abroad. Despite his advanced age,

which can hardly be guessed from his appearance, Stransky is active both scientifically and as a practicing neurologist and psychiatric expert. He enjoys the greatest admiration and esteem of the physicians of his homeland because of his witty and spirited lectures and quick repartee.

H. REISNER,
Vienna.

CHEMICAL CONCEPTS OF PSYCHOSIS

At the International Congress of Psychiatry in Zurich, Sept. 1957, a symposium, with Dr. Max Rinkel of the Mass. Mental Health Center as chairman, was held on "Chemical Concepts of Psychosis." A distinguished group representing many nations and scientific fields including biochemistry, physiology, pharmacology, psychology and psychiatry discussed the topic. The papers and discussion brought forth many new and critical observations on the progress of investigations on the psychological effects of newer chemicals. A highlight of the program was a message from Dr. Carl G. Jung, Honorary President of the symposium, which reads as follows:

"Please convey my sincerest thanks to the opening session of your Society. I consider it a great honour to be nominated as Honorary President, although my approach to the chemical solution of problems presented by cases of schizophrenia is not the same as yours, since I envisage schizophrenia from the psychological point of view. But it was

just my psychological approach that had led me to the hypothesis of a chemical factor, without which I would not be able to explain certain pathognomonic details in its symptomatology. I arrived at the chemical hypothesis by a process of psychological elimination rather than by specifically chemical research. It is therefore with my greatest interest, that I welcome your chemical attempts. To make myself clear, I consider the aetiology of schizophrenia to be a dual one, namely, up to a certain extent, psychology is indispensable to explain the nature and the causes of the initial emotions, which give rise to metabolic alterations. These emotions seem to be accompanied by chemical processes causing specific temporary or chronic disturbances or destructions."

All the members agreed that the meeting had been highly successful, assuring further marked progress in this field of experimental psychiatry.

MAX RINKEL, M. D.,
Mass. Mental Health Center.

THE SECOND INTERNATIONAL CONGRESS OF PSYCHIATRY ZURICH, SEPTEMBER 1-7, 1957

The sense and the aim of any congress is to *congregere*, that means to get together. This sense and this aim were splendidly realized in Zurich. In a truly cosmopolitan city there are many preconditions making the sojourn of visitors pleasant. I need only to refer to the multilinguality of the Swiss that makes it easy for everybody to enjoy their hospitality, and particularly, in a place like Zurich to fall into the rhythm of a beautiful city.

Our Swiss hosts would have been willing to transcend themselves in order to do justice to their guests if such transcendence would have been necessary outside of one or the other scientific discourse. They had prepared a program and other printed material—quite a bit of it, indeed, including a psychiatric issue of the *Journal Suisse de Medecine*—that facilitated orientation in time and space as far as possible. There were numerous big and small classrooms in

the University of Zurich and in the Federal Institute of Technology. There were guides and helpers everywhere and there was even plenty of parking space provided.

Heart and soul of the organization of the congress were Manfred Bleuler and his staff. Manfred Bleuler was, I daresay, the soul of the whole, although he had to move around on a cast due to a malleolar fracture that he had suffered recently. He crowned his work with the speech he gave after the Congress Dinner on Wednesday, September 4. In this speech the topic was not psychiatry but Zurich and its history. Manfred Bleuler put his whole heart into it showing his dedication to his task and his profound love for his home city.

In the scientific programm the biological and the philosophical (geisteswissenschaftliche) approach in psychiatry came to rather full expression. As regards treatment, somatic methods as well as psychotherapy had field days. Special and ethnological problems were presented too. "The Present Status of our Knowledge about the Group of Schizophrenias" was demonstrated in papers and in symposia. There were not any new discoveries revealed. There were also several exhibits but I will not go into detail.

Congress languages for the about 2500 participants coming from 57 countries were German, French, English, Spanish and Italian. It repeatedly happened that a speaker had to read his paper two or three times, everytime in another language. Manfred Bleuler, for instance, read his paper, "Aims and Topics of our Congress," on Sunday in the forenoon in French, in the afternoon in English, and on Friday morning in German.

There were almost exclusively prepared discussions, mostly read from a script by the discussants. This, in my opinion, is regrettable as it impeded spontaneous remarks.

The time factor may have played a role here. However, if before the definite formulation of the programm a goodly number of superfluous papers would have been eliminated, time enough would have been available. It occurs to me also that an International Congress should not be the exercising ground for inexperienced and boring speakers. Some criticism and selfcriticism in these respects would be very desirable.

At the meetings on Sunday the Zurich Chamber Orchestra made lovely music. Twice in the evening a serenade was performed by the Winterthur String Quartetté. A memorial plaque to Adolf Meyer was donated to the University Psychiatric Clinic Burghoelzli.

On Sunday afternoon the French psychiatrists Jean Delay and Henri Ey and our own Oskar Diethelm were appointed honorary doctors of medicine by the Medical Faculty of the University of Zurich.

Needless to say the work of Eugen Bleuler found full appreciation at a great number of opportunities.

Erwin H. Ackerknecht published a timely *Short History of Psychiatry* * from which I translate:

The great men (sc. in history) were only possible because other men worked with and before them. If there had not been a Pinel, a Kraepelin, or a Freud, other men would have accomplished their work with more or less splendor. This does not exclude the fact that these great men are the best representatives of the psychiatry of their time; hence they must be more intensively studied than is possible in a short survey.

Let us hope and pray that another Pinel or another Kraepelin or another Freud may be given to psychiatry before long.

EUGEN KAHN, M. D.,
Houston, Tex.

* *Kurse Geschichte der Psychiatrie*. Stuttgart: Ferdinand Enke. 1957, IX, 99 pp.

OFFICIAL NOTICES

TREATMENT OF ACUTE EMOTIONAL DISORDERS UNDER THE DEPENDENTS' MEDICAL CARE PROGRAM FOR DEPENDENTS OF MEMBERS OF THE UNIFORMED SERVICES

Since medical care of dependents of uniformed services personnel in civilian medical facilities began December 7, 1956, as authorized by Public Law 569, 84th Congress, it has been noted that the authorization for hospitalization of acute emergencies classified as acute emotional disorders needs to be better understood.

Treatment of nervous and mental disorders is not authorized under the provisions of the Dependents' Medical Care Act, Public Law 569, 84th Congress, except in special and unusual cases (see Sec. 103(g)(2) and Sec. 204).

The authority given to make exceptions for hospitalization of patients for nervous and mental disorders in uniformed services medical facilities requires some explanation. The Surgeon General of the respective uniformed service is authorized to treat dependents with acute emotional disorders in uniformed services facilities and to transfer eligible dependents from civilian to uniformed services facilities for treatment of such disorders. However, few beds are available for women and children in uniformed services facilities for the treatment of nervous and mental disorders. In general, they are sufficient only for female uniformed service members and for dependents having N-P disorders who are evacuated from outside continental United States.

The need to provide civilian facilities for cases of acute emergency, including acute emotional disorders was met by the Joint Directive; "Hospitalization is authorized at Government expense for such emergencies only pending completion of arrangements for care elsewhere" unless the illness qualifies for hospitalization under another provision of the law, such as pregnancy. This is interpreted to mean that the Government is liable for payment of the hospital and physician's

bills only: a. until the acute emotional disturbance subsides; or b. until the sponsor can arrange for care at other than Government expense, whichever is earlier.

The judgment and integrity of the attending physician must be relied upon to determine when the acute emotional disturbance subsides, also the probable duration of hospitalization required, and his word will be unquestioned, unless there is evidence to the contrary.

For a practical working arrangement, Fiscal Administrators may handle many cases without referral to the Office for Dependents' Medical Care. Bills may be paid without further reference: a. if the physician states the condition was one of acute emotional disorder constituting an emergency requiring hospitalization for the life, health or well being of the patient, regardless of psychiatric diagnosis; and b. if the duration of hospitalization did not exceed 21 days.

When the Government's liability terminates not later than 21 days, the DA Form 1863 for the physician and hospital should show the type of disposition which has been made. This will aid contractors in making prompt payments.

Extension of medical care beyond 21 days at Government expense may be granted only by the Contracting Officer, Office for Dependent's Medical Care for short periods, for the following reasons:

(1) When there is necessity for more time for the sponsor to assume responsibility. Examples: (a) Sponsor's return from overseas station, sea duty, etc.; (b) Difficulty in obtaining agreement of state or municipal institution to accept patient.

(2) When retention in the hospital for two or three weeks will result in a cure or remission which will permit patient to return home.

(3) When diagnosis for determination of length of care cannot be made within the 21-day period.

A suggested procedure for requesting an extension of hospitalization beyond 21 days follows:

(1) Upon admission of a patient under the Dependents' Medical Care Program, the hospital administrator should immediately contact the charge physician to ascertain the length of time hospitalization will be required for the acute emergency.

(2) If the attending physician is of the opinion that hospitalization will be required beyond a 21-day period, the hospital administrator should immediately prepare a report containing information specified in subparagraph (3) below and forward to the Contractor (Blue Cross or Mutual of Omaha, whichever is applicable). Because of the shortness of time, this report should always be submitted by the end of the first 7 days of hospitalization and should be forwarded by air mail by all echelons, if more expeditious.

(3) The report will be clinical and will show the name of the dependent, date of admission, diagnosis, prognosis, service member's name, serial number, branch of service, the physician's name, and the length of time for which extension of hospitalization at Government expense is requested with reasons therefor.

In cases when extensions of time beyond 21 days are granted by the Contracting Officer, the DA Forms 1863 submitted by the hospital and physician must have attached thereto a copy of the Contracting Officer's authorization.

Procrastination and delay on the part of an available sponsor to arrange for care of the patient at other than Government expense will in no case be considered reason for extension of the 21-day period.

On receipt of request for extension of medical care beyond 21 days, the Contracting Officer will determine if facilities are available for further care in uniformed services facilities and if so, will notify the contractor. If an extension of time is not justified or uniformed services facilities are not available, the Contracting Officer will notify the contractor of the date when the Government's liability for payment did or will terminate.

Physicians accepting patients with acute emotional disorders under the Dependents' Medical Care Program have the great responsibility of making recommendations which are compatible with the Law governing the Program. They must determine that the acute emotional disorder is one which constitutes an acute emergency and that hospitalization is necessary for the life, health or well being of the patient. They should institute treatment as indicated and at the same time begin discussions with the sponsor which will lead to the proper treatment and care of the patient at other than Government expense.

PAUL J. ROBINSON,
Major General, M. C.
Executive Director,
Office for Dependent's
Medical Care.

HAPPINESS

Happiness in this world, when it comes, comes incidentally. Make it the object of pursuit and it leads us a wild-goose chase, and is never attained. Follow some other object, and very possibly we may find that we have caught happiness without dreaming of it; but likely enough it is gone the moment we say to ourselves, "Here it is!" like the chest of gold the treasure-seekers find.

—NATHANIEL HAWTHORNE

NEWS AND NOTES

PSYCHOPHARMACOLOGY SERVICE CENTER, N.I.M.H.—A clearinghouse of information on psychopharmacology is being established by the Psychopharmacology Service Center of the National Institute of Mental Health. An extensive collection of the literature in this field, including pharmacological, clinical, behavioral, and experimental studies of the ataraxic, psychotomimetic, and other centrally acting drugs, will be classified and coded to enable the staff to answer a wide variety of technical and scientific questions. As soon as enough materials have been assembled the Center plans to offer bibliographic and reference service as well as the preparation of critical and analytic reviews of special topics in the field.

In order to accelerate the growth of the literature collection the Center invites persons working in this field to provide 3 copies of any papers that deal with their work—whether reprints, pre-publication manuscripts, progress reports, informal mimeographed reports, papers read at meetings, or abstracts. Letters outlining work in progress would also be welcome. Any restrictions that authors may wish to place on the Center's use of their papers will be strictly observed. All materials should be addressed to the Technical Information Unit, Psychopharmacology Service Center, National Institute of Mental Health, 8719 Colesville Road, Silver Spring, Md.

WESTERN DIVISIONAL MEETING, A.P.A.—The 4-day meeting of the Western Division of The American Psychiatric Association, in conjunction with the West Coast Psychoanalytic Societies, will be held in Los Angeles, Cal., November 20-24, 1957. More than 2,000 physicians from the Western United States and Canada are expected to attend.

Papers to be presented will be grouped in the following categories: Group Psychotherapy, Experimental Psychiatry, Psycho-

somatic Medicine, Hospitals, Drugs, Individual Psychotherapy, Social Psychiatry, Child Psychiatry, and Psychoanalytic Papers.

Delivering the Academic Lecture, November 23, will be Ralph W. Gerard, M. D., Ph. D., Professor of Neurophysiology at the University of Michigan School of Medicine. Other guest speakers: Franz Alexander, M. D., Los Angeles; Sydney Margolin, M. D. and René Spitz, M. D., Denver, and author Aldous Huxley.

For further information contact Robert A. Solow, M. D., 427 North Camden Drive, Beverly Hills, Cal.

FINANCIAL AID TO MENTAL HEALTH STUDENTS.—The staff of the Southern Regional Education Board has compiled a brochure listing grants, fellowships, stipends and scholarships available in the South for training in the mental health professions: psychiatric social work, psychiatric nursing, psychiatry and clinical psychology. The material was secured from institutions and agencies in the 16 states included in the Southern Regional Education Compact. It lists 1,042 such grants amounting to \$2,653,700 per year in all the disciplines.

Copies of the brochure may be obtained on request from: Southern Regional Education Board, 881 Peachtree St., N.E., Atlanta 9, Ga.

AMERICAN OCCUPATIONAL THERAPY ASSOCIATION.—The Association celebrated its 40th anniversary with the Annual National Institute Conference held October 21-25 in Cleveland, Ohio. Occupational therapists from all over the United States participated in the program.

Emphasis was placed on group techniques and the occupational therapist's role in the therapeutic situation. A panel, consisting of representatives from several allied profes-

sions, as well as occupational therapy, discussed the evaluation of the patient.

The opening address was given by Henrietta McNary, O.T.R., Director of Occupational Therapy, Milwaukee-Downer College. Louis Seltzer, Editor of the Cleveland Press, was speaker at the banquet.

5TH INTERNATIONAL CONGRESS OF INTERNAL MEDICINE.—The 5th Congress of the International Society of Internal Medicine will be held in Philadelphia, April 23-26, 1958. Those physicians in North and South America who wish to become members of the International Society and to attend the Congress should request application forms from E. R. Loveland, Secretary-general of the 5th Congress, 4220 Pine St., Philadelphia 4, Pa. Dues are \$5.00 for a 2-year period. Physicians in other countries should write to Professor H. Ludwig, 2, Med. Aberlung Burgospital, Basel, Switzerland.

Anyone who wishes to participate in the program should send the title of his paper and a 200 word abstract, in triplicate, to Dr. Frank N. Allan, 605 Commonwealth Ave., Boston 15, Mass.

AMERICAN PUBLIC HEALTH ASSOCIATION, INC.—The Association is initiating a long-range technical development program to provide leadership and guidance to governmental and voluntary agencies, in the health problems of the nuclear age. "In some important areas of public health," states Dr. Reginald M. Atwater, executive secretary, "methods and standards have remained virtually unchanged since the horse-and-buggy era."

Initial concentration will be in 8 areas: radiological health, accident prevention, mental health, chronic disease and rehabilitation, child health, environmental health, medical care administration and public health administration.

To coordinate the program, a technical development board has been appointed. Chairman is Dr. Martha M. Elliot, former chief of the U.S. Children's Bureau and now professor of maternal and child health at the Harvard School of Public Health, Boston.

The present program is the first step in a

3-year expansion and reorganization program for the 85-year-old professional society. The Rockefeller Foundation has made a grant of \$150,000 to help finance the new activities.

Among listed priority health needs is the maintaining of a full attack on the major unsolved health problems: cardiovascular diseases, mental diseases, crippling and handicapping conditions, cancer, dental diseases, diabetes and alcoholism.

The American Public Health Association is the largest professional organization of public health workers in the Western Hemisphere, its 13,000 members including physicians, nurses, dentists, veterinarians, engineers, sanitarians, statisticians, nutritionists, biologists, health educators, institutional administrators and other specialists on staffs of governmental and voluntary agencies.

Headquarters of the Association: 1790 Broadway, New York City.

President: Dr. John W. Knutson, assistant surgeon general and chief dental officer, U.S. Public Health Service.

BIBLIOGRAPHY OF MEDICAL REVIEWS, VOL. 2.—Thirteen months after the publication of the experimental Bibliography of Medical Reviews, 1955, volume 2 appeared in August. The Bibliography will be continued as a regular annual publication of the National Library of Medicine.

Complete entries including the bibliographic reference and translation of foreign titles, appear under the various subject headings, with plentiful cross references. This issue contains about 1800 review articles, all material being culled from journals indexed in the Current List of Medical Literature.

Copies are available from the Superintendent of Documents, Government Printing Office, Washington 25, D.C., at 60¢ per copy.

DR. WARNER HEADS CRAIG COLONY.—Dr. George L. Warner, assistant director of Marcy (New York) State Hospital, has been appointed director of Craig Colony, state hospital for epileptics in Sonyea, N.Y., and assumed his new duties September 26, 1957. He succeeds Dr. William C. Johnston, who

has returned to his former post in the Department of Correction.

Dr. Warner has been at Marcy State Hospital for the past 14 years, and with the Department of Mental Hygiene 34 years. He is a diplomate of the American Board of Psychiatry and currently president of the Mohawk Valley Neuropsychiatric Society.

NATIONAL FOUNDATION FOR INFANTILE PARALYSIS.—One of the newly announced grants by the National Foundation will be for research in vaccines to protect the human nervous system against invasion by viruses. Dr. Jonas E. Salk will direct this research at the University of Pittsburgh.

Under another of the grants, the Rockefeller Institute for Medical Research will continue their investigations of drugs for the treatment or prevention of polio crippling.

Studies of possible live-virus vaccines will go on at Yale University under another grant. After preliminary injections of Salk vaccine, the subjects will receive weakened strains of virus by mouth—so-called live-virus vaccines.

TREATMENT OF JUVENILE DELINQUENTS, CALIFORNIA.—Recently the State of California has authorized the establishment of a special treatment program for juvenile delinquents with psychiatric problems who are in need of longterm treatment. Special units whose efforts will be devoted entirely to treatment are now being organized within one correctional school for boys and one for girls. Each treatment unit will consist of a psychiatrist as director, plus the necessary number of clinical psychologists, case and group workers, who will make maximum use of all modern treatment methods. It is estimated that these special problem cases constitute approximately 15% of all youths admitted to Youth Authority institutions.

DES MOINES CHILD GUIDANCE CENTER.—The Center will inaugurate a "Day-Hospital" project under a grant from the National Institute of Mental Health. Aim of the project is three-fold: 1. To provide an intensive therapeutic program to reduce some of the psychological and economic difficulties involved in hospitalization. 2. To make pos-

sible intensive diagnostic study and treatment for children with mixed disorders (*e.g.* physical handicap and neurotic disorder). 3. To evaluate systematically the relative effectiveness of day-hospital and outpatient care for children.

A new building for both day-hospital and outpatient services will be erected adjoining Raymond Blank Memorial Hospital, a teaching hospital in pediatrics.

A brief description of the project is available by writing to: Howard V. Turner, M. D., Medical Director, Des Moines Child Guidance Center, Des Moines 9, Iowa.

CEREBRAL VASCULAR DISEASE AND STROKES.—This is the title of a new illustrated publication on disease of blood vessels of the brain, just released by the Public Health Service (Publication no. 513). The booklet shows the 5 important ways in which vessel diseases impair the working of the brain and outlines steps involved in treatment and rehabilitation.

A free copy may be obtained from the Heart Information Center, National Heart Institute, Bethesda 14, Md.

STUDY CENTER FOR MENTALLY RETARDED CHILDREN, BUFFALO, N.Y.—A grant of \$45,000 to establish the Buffalo Diagnostic and Counselling Study Center for Mentally Retarded Children was announced by Raymond W. Houston, chairman of the New York State Interdepartmental Health Resources Board. The Center will be an integral part of the Rehabilitation Center of the Children's Hospital and Crippled Children's Guild at 936 Delaware Avenue, Buffalo, N.Y.

Complete evaluation, diagnosis and treatment will be offered to mentally retarded children. Parent counselling and guidance in planning a definite program for the child will be a major goal. Other features of the program are teaching medical students, nurses, psychologists and social workers modern techniques of treatment, evaluation and diagnosis of mental retardation.

Dr. Robert Warner, Director and Coordinator of the Rehabilitation Center, will direct the new Study Center.

SOCIAL WORK GRANTS, UNIVERSITY OF DENVER, COLO.—Federal grants amounting to \$59,787 have been allocated to the University of Denver School of Social Work, 1957-58 term. The grants will be used to maintain an expanded program for the education of psychiatric social workers, and to prepare social workers for state vocational rehabilitation programs, hospitals, clinics, adjustment centers for the blind and crippled children's services.

AMERICAN PUBLIC HEALTH ASSOCIATION ANNUAL MEETING.—At the 85th annual meeting to be held in Cleveland, Ohio, November 11-15, 1957, there will be ample representation of all the problems of mental health. Most of the papers to be presented on this subject emphasize community mental health problems, and the need to educate the public to the problems of the mentally ill. Some of the topics listed are "Intramural Psychiatry in Public Schools," "Health Department Participation in a Developing Community Mental Health Program," and "Mental Health Aspects of Environmental Resources and Complexes." Dr. Rema Lapouse, associate in psychiatry and preventive medicine and public health at the University of Buffalo, and secretary of the mental health section of the American Public Health Association, counts on a wide response on the part of psychiatrists and associated workers in the field of mental health, to the 5-day program.

WORLD MEDICAL PERIODICALS.—The 2nd edition of *World Medical Periodicals* published by The World Medical Association, became available in October, 1957. The first edition, published by UNESCO and WHO, appeared in 1953. As a result of continued revision during the past 2 years, some 1,400 new titles have been added and 600 omitted. The new edition contains the titles of medical, pharmaceutical, dental and medical veterinary periodicals in existence at the beginning of 1957, and also a few well known periodicals which have ceased publication since 1900 but to which reference is frequently made in current medical bibliographies.

The new appendices give: 1. a list of the principal international abstracting journals and 2. a list of the main international periodical indexes.

Other new features include the International Code for the abbreviation of titles of periodicals as issued in 1954, and the making of the index of periodicals by subject more useful in grouping the index numbers by countries.

One objective of the publication, *World Medical Periodicals* is to provide medical editors and publishers with abbreviations of the periodicals listed which had been determined by an accepted medical code, thereby securing uniformity in one particular detail of medical bibliography.

The editorial office: *British Medical Journal*, BMA House, Tavistock Square, W.C.1, London, England.

WHICH ACADEMIC CAREER?

... philosophical activity as a *business* is not normal for most men, and not for me. To be responsible for a complete conception of things is beyond my strength. To make the *form* of all possible thought the prevailing *matter* of one's thought breeds hypochondria. ... But as my strongest moral and intellectual craving is for some stable reality to lean upon, and as a professed philosopher pledges himself publicly never to have done with doubts on these subjects, but every day to be ready to criticize afresh and call in question the grounds of his faith of the day before, I fear the constant sense of instability generated by this attitude would be more than the voluntary faith I can keep going is sufficient to neutralize. ... A 'philosopher' has publicly renounced the privilege of trusting *blindly*, which every simple man owns as a right—and my sight is not clear enough for such constant duty. Of course one may say, you could make of psychology proper just such a basis, but not so, you can't divorce psychology from introspection, and insecure as is the work demanded by its purely objective part, yet it is the other part rather for which a professor thereof is expected to make himself publicly responsible.

—WILLIAM JAMES
(*Diary*, act. c.30)

BOOK REVIEWS

PSYCHICAL RESEARCH. By R. C. Johnson. (New York: Philosophical Library, Inc., 1956. pp. 176, \$2.75.)

The review of a book on psychical research in a psychiatric journal implies that this "subject" has some relevance to psychiatry. The question is: Does it? The basis for our answer should be carefully weighed. According to the proponents of parapsychology, their work has relevance not only to psychiatry, but to most other scientific and practical endeavors as well. This reviewer, however, is of the opinion that writings on parapsychology are compounded of various manifestations of the all-too-human inability to tolerate object loss with a profound epistemological confusion concerning inquiry, language and science. This book only confirms the reviewer's foregoing position toward psychical research. Still, there is a persistent interest among psychiatrists in this subject, and an equally persistent claim for the psychotherapeutic relevance of telepathy in various quarters. These "social facts" amply justify critical evaluation of such material.

The contents of the book can be best described by listing the titles of the 10 chapters: "I. History of Psychical Research, II. Telepathy and Clairvoyance, III. Precognition and Retrocognition, IV. Object-reading or Psychometry, V. Psycho-kinesis and Poltergeist Phenomena, VI. Materialisation Phenomena, VII. Apparitions and Hauntings, VIII. Mediumship, IX. The Problem of Survival, X. The Importance of Psychical Research." No new raw observations, or "data," are provided. The author's ideas are based on the writings of others and his own thinking about these problems. A few illustrative passages will be quoted, since the "atmosphere" of the book and its author's thinking can probably be best conveyed in this fashion.

"It is almost ironical that the labours of psychical research have enlarged our knowledge of the mind's powers, and by implication made the essential dependence of mind on matter seem less and less plausible" (p. 158).

"My own considered view is this: that responsible individuals with caution and persistence can, and have, satisfied themselves of the survival by intimate friends of the death of the body. I confess that this is my own conviction in relation to an intimate friend of mine who died some ten years ago. I consider, however, that this kind of conviction is personal and cannot be handed on to others. When, however, we look at the issue of survival objectively, the cumulative evidence strongly supports the survival hypothesis as by far the most plausible" (p. 159).

"If, as I believe, the so-called material world is a creation of Mind (with the aetheric world an intermediate creative stage), then it is on the level of Mind that the prototype of the material level exists. When a man no longer retains awareness

of the material level, whether in sleep by a temporary inward withdrawal of consciousness, or whether by discarding his body at death, consciousness is refocused on an interior level, i.e., one which is a step nearer to the ultimately real. This new world-level then acquires objectivity for him" (p. 161).

"It will be clear that the zone or level between the mental and the material, which in this book we have labelled aetheric, must be one of great importance to physical health" (p. 168).

The author concludes with the following paragraphs:

"Today, most if not all of the miracles can be accepted as credible in the light of the phenomena considered in this book. Powers of the mind which we have come across already, if fully under the control of the will, would be capable of performing these miracles. Our concept of the term "miracle" would then be of an unusual physical event, inexplicable on the basis of current laws of the physical world, but wholly "natural" as an exercise of the powers and energies of the mental level. I can see no reason why Religion should not view Psychical Research as a friendly fellow-traveller in the search for Truth. Psychical Research is primarily a search for Truth by the well-established scientific method of experiment and by the traditional method of analysis of testimony common to such disciplines as law and history. Its field extends between the familiar material world we know through our senses and the so-called subjective world of Mind. Behind the levels of Mind are unplumbed depths of being which take us nearer to the ultimately Real. But this is the territory—awesome, fascinating, rapturous, and infinitely more important—of the Mystics" (p. 173).

The author, like many parapsychologists, raises the question of survival after death. Belief in this, setting aside its psychological determinants, is based on, and illustrates, a rather primitive sort of error in reasoning. This reasoning—in the reviewer's opinion—runs something like this. "I" can lose my arm or leg, or even my eye, and still "I" remain. In other words, one can lose parts of one's body, and still feel that one's sense of identity has remained unchanged. Accordingly, the reasoning seems to be: If I can lose this or that part of my body and still retain my (sense of) identity, why should it not be possible to lose my entire body, and still retain my "self?" Indeed, belief in the verity of this outcome has probably played an important part in the seeking of joyful death by religious martyrs. For such a person, death is not "death," but a voyage to Paradise. No doubt, man's ability to tolerate, and to accept, object loss, including the loss of one's own body and self, is frequently limited. And the struggle for its mastery gives rise to all sorts of human activities, some more, some less useful; the word

"useful" here refers to something more than merely the restoration of the lost sense of well being. Human activities having some pertinence to this problem thus encompass, among others, science, religion, fiction and paranoid pseudo-science. This book, and many others dealing with "psychical research," may be regarded, therefore, as posing an interesting—and perhaps for some people, an important—challenge in distinguishing between good science, bad science, science fiction and paranoid system building. It behooves authors, publishers and the intelligent reading public alike to consider what material falls in which category and to know the reasons for their choice.

Syracuse, N. Y.

MENTAL HYGIENE (Revised Edition). By D. B. Klein. (New York: Henry Holt & Co., 654 pp., 1956. \$6.75.)

This revised edition, including 654 pages, is aimed at enlightening the general public, and to create a climate of awareness of its mental health needs. It contains a glossary of terms, and a complete index. Bibliographic references appear as footnotes.

The book is divided into 4 parts. The first is an introduction embracing comments upon the nature and scope of mental hygiene. The author calls attention, as others have, to the fact that mental hygiene or mental health enters into every phase of human activity. It constitutes a problem, therefore, not only as a challenge to modern medicine and its auxiliary disciplines, but also to the legal and educational professions; to legislators and statesmen; to the sociologist and the industrialist; to the psychologist and the clergy; and to community and civic leadership concerned with the development of an enlightened and articulate public opinion on this subject matter. Part I also briefly reviews the history of the so-called "mental hygiene movement" and some of the problems with which mental hygiene is concerned.

Part II reviews the status of knowledge concerning the nature of mental disorders and the understanding of abnormal behavior; separating and discussing, on the one hand, those disorders associated with structural brain changes, or situations that interfere with brain cell nutrition; and those on the other hand that have long been designated as functional in origin.

Part III is concerned with the subject of prevention, of prophylaxis, or situation that hinders the development of psychiatric disorders. This particular situation is approached by reference to the numbers and percentages in each diagnostic category of patients admitted to state and private mental hospitals. The author is not too optimistic respecting the prevention of those disorders associated with organic or structural brain changes, nor is he cheerful about preventing those of a functional nature in the light of the present state of knowledge. He deplores the paucity of available funds for the support of concerted research in the mental health fields, but envisages the day, when such research

becomes effective, that mental hygienists will be able to substitute "the certainty of touch that comes with the accumulation of tested knowledge." "Without a solid foundation of such tested knowledge the prophylactic campaigns of the mental hygienist will continue to be more of a tribute to his earnest hopes than a record of positive accomplishment."

However, the book gives very little space to a consideration of the role which the formulation or modification in public policies toward the mentally ill, and their administration, may play in the prevention of such illness; particularly with reference to their early detection and the application of measures for their treatment or amelioration. Perhaps, in the light of the present knowledge, this latter approach may be, for the time being, the foundation upon which the superstructure for the prevention of mental illness must be built. The author concedes that progress has been made, for an insight into the nature of these problems and an appreciation of their complexity is more profound than that of the "alienists" of earlier generations. Considering how little money society has devoted to research, those responsible for what progress has been made are all the more deserving of gratitude.

Part IV deals with the promotion of positive mental health. This is approached from the standpoint of personality growth and development and its emancipation. The author asserts that the development of the positive aspects of good mental health is intimately related with emotional security having its roots in the life of home and family. He recognizes the fact that the personality of each and every person is the result of what the world and its people have done to him today, yesterday, and the days before. He does not rigidly adhere to the doctrine that personality development is exclusively determined by parent-child relationship and permanently fixed by experiences of early infancy and pre-school years. He recognizes, therefore, that the education and socialization of children is not limited to the home or early developmental years, and that there is not always but one right way to rear children.

Borrowing from Havighurst, the author discusses personality development for promoting positive mental health from the standpoint of goals to be sought: such, for example, as (a) patterns of behavior respecting dependence and independence; (b) to give and receive affection; (c) to deal with different social groups; (d) to assimilate and acquire a moral code and an ethical sensitivity; (e) to acquire appropriate attitudes toward sex roles and toward masculinity and femininity; (f) to accept characteristics of physical growth and development; (g) to develop increasing effectiveness in muscular skills; (h) to accept and become increasingly familiar with the physical world; (i) to acquire increasingly effective modes of communication, accurate concepts and reasoning skills; and (j) to feel at home in the universe.

The author comments upon the dangers of over dependence of psychology and upon conflicting teachings and the perspectives of parents and teachers. He also discusses in the section devoted to the development of a balanced personality the dynamics

of conscience; the role of home fixation to functional autonomy; the coping with reality; and the Utopian aspects of a program for promoting the positive aspects of mental health. He believes that repression is an important factor in personality integration, and comments, "Life being what it is, repression of some sort is not only necessary but inevitable."

The book closes with a comment on the significance of religious teaching and the role which the so-called "old fashioned virtues" may play in promoting positive mental health.

On the whole this book is a praiseworthy contribution and should fulfill a need for which it was written.

W. L. T.

EPILEPSY AND THE LAW: A PROPOSAL FOR LEGAL REFORM IN THE LIGHT OF MEDICAL PROGRESS.
By Roscoe L. Barrow, and Howard D. Fabing.
(New York: Hoeber-Harper, 1956. \$5.50.)

With the recent publication of *Epilepsy and the Law* a tremendous step has been taken toward correcting the many archaic laws that have contributed to the stigma associated with epilepsy. Epilepsy laws have lagged far behind medical progress in understanding epileptic phenomena and controlling the symptoms. The special committee on legislation of the American League Against Epilepsy, aided by a grant from the National Institute of Neurological Diseases and Blindness, sponsored a survey of laws and administrative practices affecting epileptics. Dean Roscoe L. Barrow, University of Cincinnati School of Law, and Dr. Howard D. Fabing have collaborated in a scholarly and exhaustive review of the laws of the 48 states with respect to marriage, driver's licenses and employment of epileptics. They show that the existing laws were enacted at a time when even the medical view held that the etiology of seizures was unknown, seizures were incurable, the condition was accompanied by progressive mental deterioration and progeny of epileptics was likely to have seizures. Many states (13 at the present time) have laws making marriage of persons with epilepsy a crime, making their sterilization mandatory or permissible, and which bracket epilepsy with insanity, and mental retardation as sufficient cause for custodial care. Wisconsin has recently initiated legislative reforms by repealing laws of sterilization of epileptics, of marriage prohibition, of compulsory reporting and is revising its policy on driver's license. Revision of workmen's compensation laws remains to be enacted. The report is well indexed so that each state's position in respect to the various laws may be quickly found. Pointing out problems does not automatically correct them. Included, therefore, is a blueprint for modernization of legislation which discriminates against epileptics.

Boston, Mass.

J.A.M.A. CLINICAL ABSTRACTS OF DIAGNOSIS AND TREATMENT. American Medical Association.
(New York: Grune & Stratton, Inc., 1956, pp. 661. \$5.50.)

This volume presents a large number of abstracts emphasizing diagnosis and treatment selected from the "Medical Literature Abstracts" section of the J.A.M.A. One naturally compares it with other abstract annuals and finds its coverage much broader—replacing several volumes. As well as covering the 10 body systems there are chapters on eye, ear, nose and throat, metabolism, poisonings, infections, therapeutics, and diagnostic techniques. This reviewer feels some brief editorial comments by experts in the various fields would be a valuable addition.

The volume should be of value to the general practitioner, or the specialist with broad interests; (a) if he had been negligent of the literature but took time for this quick method of review for 1955, or; (b) wished to look up recent articles on some particular subject. One could locate almost any subject in the index and, depending on the amount of recent progress, find one or more abstracts reviewing current experience and thought.

W. T. W. CLARKE, M.D.,
Toronto, Canada.

CLINICAL EXAMINATIONS IN NEUROLOGY. By James A. Bastrom and others. Sections of Neurology, and Section of Physiology, Mayo Clinic, and Mayo Foundation. (Philadelphia: W. B. Saunders Co., 1956. \$7.50.)

This text is an excellent example of the recording of the techniques in examination of the nervous system, selected by a number of neurologists over more than the past 50 years. These men have had the opportunity of working as a "guild" and thus contended, with a minimum of competition, to divert the truly scientific interest in acquiring the most efficient techniques for their performance of a neurological examination.

There is nothing revolutionary in the presentation, but it is noteworthy that the treatment of each chapter is extremely thorough. The neurological history is covered in 2 chapters, and the latter sets out the use of the Mayo Clinic neurological charts used for recording.

A chapter is devoted to neuro-ophthalmology in which the cranial nerves associated with eye and pupillary movements are considered, as well as the optic nerve. Motor function is given 2 chapters. The latter describes the specific study of muscle.

In treating the examination of mental function, it is refreshing to find a neurological text that does not involve itself with a pseudo-psychiatric examination, and present this as a neurologist's assessment of mental function. The chapter on clinical examination in selected problems of pain is a novel treatment and is extremely practical.

The members of the section of psychology have contributed 2 excellent chapters—one on electroencephalography, and the other on electro-myography. Sufficient basic science is included to ex-

plain the nature of the modalities measured and the responses to be expected in the various more common neurological diseases.

Chapter 16 provides a well systematized reference for pharmacological and biochemical aids in the neurologic diagnosis of altered states of consciousness (including convulsive disorders), headache, muscular weakness, polyneuropathy, Wilson's disease and diabetes insipidus. The final chapter on spinal fluid examination by lumbar and cisternal puncture completes this comprehensive text.

This volume should be of great value to the student and no doubt, will be prized in any neurologist's library. It is indeed fitting that a work of this calibre was inspired by 2 of our outstanding pioneers in American Neurology, namely, Henry W. Woltman and Frederick P. Moersh.

LORNE D. PROCTOR, M.D.,
Henry Ford Hospital.

ATLAS OF NEUROPATHOLOGY. By *Nathan Malamud, M.D.* (San Francisco: University of California Press, 1957, pp. 468, \$20.00.)

The photography of both the gross and the microscopical specimens illustrated in this comprehensive atlas is excellent. It is of interest that, apart from two pages of colour photo-micrographs, the author has found black and white photography to be adequate throughout.

The atlas illustrates and describes nine types of disorders, after a preliminary chapter on Cytology and Cellular Pathology, under the titles of inflammatory, toxic and nutritional, demyelinating, vascular, traumatic, degenerative, neoplastic, developmental and a final important chapter on Sequelae of Paranatal and Postnatal Disorders. The chapter sub-headings combined with a good index make the book easy to use.

It will prove a valuable reference work on the shelves of general and special medical libraries, and it should be available in all laboratories in which undergraduate and graduate neuropathology is taught.

ERIC A. LINELL, M.D.,
University of Toronto.

THE YEAR BOOK OF NEUROLOGY, PSYCHIATRY AND NEUROSURGERY 1956-1957 SERIES. Edited by *Roland P. Mackay, M.D.* (Neurology), *S. Bernard Wortis, M.D.* (Psychiatry), *Oscar Sugar, M.D.* (Neurosurgery). (Chicago: The Year Book Publishers, 1957. \$7.00.)

With its 56th year of publication this Review records another change in its editorial staff. Ten years ago a section on neurosurgery was introduced in the Year Book under the editorship of Percival Bailey. This year Oscar Sugar, who for the past 3 years and more shared editorial duties with Dr. Bailey, has taken over the responsibilities for this section. The continued policy, as Dr. Sugar states, "is to select current articles of significance and abstract them in length sufficient to be useful even without reading the original." Special atten-

tion is to be given to important articles in foreign journals. Sugar makes timely comment on the serious handicaps in communication between languages. One suggestion offered is that the National Library of Medicine in Washington, when newly housed, might establish a center for coding world literature that would in some degree reduce this handicap. Certainly the ability to read other languages beside one's own should be a required feature of medical education.

The editor notes that the past year has shown particular interest in "surgery of involuntary movements, vascular lesions, hypothermia, ultrasound and whiplash injuries of the cervical spine. There is a notable decline in interest in sympathectomy for hypertension and Raynaud's disease, operations on the eighth nerve for Ménière's syndrome and lobotomy for mental diseases."

Mackay introducing the section on neurology emphasizes the necessity not only of cultivating clinical neurology but of stimulating basic anatomic and physiologic research for the benefit of psychiatry as well as neurology, and in line with the truism: "no psychosis without neurosis." Such investigations embrace the whole range of neurologic function "from sensory nerve endings to muscle contraction, and in particular deal with the organization of sensory data and the formulation of behavior."

In this context the editor calls attention to the work of D. C. Sinclair of Oxford "which destroys much of the doctrine of specific energy" in the transmission of sensory impulses.

Again, the experience, or reported experience of pain is of "such complexity as all but to defy analysis." It is comprehensively dealt with, "from anatomy to philosophy" in a French symposium edited by Alajouanine (*La Douleur et les Douleurs* Paris. Masson et Cie, 1957).

While the last word concerning immunity against polio by means of vaccines has not been spoken, Mackay sums up: "At present there is no doubt that the Salk vaccine, properly given, confers a great and effective immunity, without significant hazard. Thus a victory over poliomyelitis is confidently expected, if only the vaccination of the population en masse can be accomplished."

Familial multiple sclerosis is dealt with in a remarkable report by a Swedish observer, Bengt Estborn, who describes 40 illustrative families, one striking example being the occurrence of the disease in 2 sisters, 1 brother, the mother and an uncle.

Concentrating on the gaps in our knowledge of the relationships between convulsive disorders and the EEG, Mackay remarks that probably "when all this is learned, we shall discover that all epilepsy is one, that all persons are capable of having seizures and differ from one another in this regard only in their degree of readiness ('threshold') for the process, that so-called etiologic factors are only trigger mechanisms, and that the types of seizures are determined solely by the locus of the discharging lesion."

In the section on psychiatry Bernard Wortis notes

the extraordinary swing to psychopharmacology in the treatment of mental disease. The ataraxics (tranquilizers) now top the list of therapeutic agents, and in many institutions have contributed notably to the solution of the overcrowding problem. Much needed studies in the differential evaluation of these drugs in their numerous modifications and combinations are also reported and the need for further research and controls emphasized.

The mental disorder of the year has undoubtedly been schizophrenia, which is more often spoken of in the plural than the singular, or better still as a schizophrenic reaction. This category has received more attention than any other psychotic group, from the standpoints of nosology, treatment, and research. Wortis calls attention to the work of Heath who reported schizophrenic-like reactions in humans by administration of a substance (taraxein) extracted from the serum of schizophrenic patients. Another experimental study by Akerfeldt of Sweden, which may be of diagnostic value, showed a high frequency of positive serological reaction in schizophrenic patients to the dye N.N. Dimethylphenylene. These and other experimental studies require further extension.

Among the most important research reports of the year were those in the genetic symposium at the annual meeting of The American Psychiatric Association. They were those on "Genetic Principles in Human Populations" by H. J. Muller, "The Molecular Basis of Genetics" by Linus Pauling, and "The Genetics of Human Behavior" by Franz J. Kallman (All in *Am. J. Psychiat.* Jan. 1956).

A feature of Wortis' introductory remarks is a series of fairly long selected bibliographies covering drug studies and the various other departments of psychiatric inquiry.

The division of the Year Book on neurology and neurosurgery is illustrated. As usual the volume offers a good representative coverage of the fields dealt with.

C. B. F.

TABOO. By *Franz Steiner*. With an Introduction by *E. E. Evans Fritchard*. (New York: Philosophical Library, 1956. pp. 154.)

In *Totem and Tabu* Freud provided the most brilliant analysis of the meaning of taboo that anyone has ever written. *Totem and Tabu* is often dismissed as a "just so" story, and, perhaps, for the most part it is. But what is sometimes forgotten is that it contains some of the most exciting examinations of the nature and function of certain historically and anthropologically interesting ideas to be found anywhere in the literature. Among these ideas is that of *taboo*. Freud is extremely illuminating on this subject, but it has remained to the late Franz Steiner to write by far the best study of the subject that we have.

Steiner's critical examination of the relevant theories and the material writings, which have been related to the study of *taboo*, Steiner brings his excellent analysis of its meaning and significance to a successful conclusion, making the double

function of *taboo* crystal clear. That double function is first, the identification and classification of transgressions, and second, the institutional localization of danger.

This is a first-rate book of great value to all students of the human mind. The death of the author in the autumn of 1952 at the early age of 43 robbed anthropology in particular and the social sciences generally of a distinguished contributor. This book will serve to keep his memory green as long as the interest in this subject endures.

M. F. ASHLEY MONTAGUE, PH. D.,
Princeton, N. J.

CURRENT THERAPY 1957. Edited by *Howard F. Conn, M.D.* (Philadelphia: W. B. Saunders Co., 1957, \$11.00.)

The latest edition of *Current Therapy* has been carefully prepared as usual.

The policy of having many new contributors to each year's volume has the effect of maintaining freshness for the reader as well as giving a wide opinion in the subjects.

The editors and consultants wisely make the point that no treatment should be considered unless the diagnosis is clear and a book on therapy alone will not appear to minimize that tremendous problem. Many of the contributors, therefore, have written a preamble to their particular subject stating the principles of diagnosis and the fundamentals on which therapy must be based.

Good examples are the article on Hypertension by Horace Smith, that on Neurocirculatory Asthenia by Donald Ross, and that on Pernicious Vomiting of Pregnancy by Nicholson Eastman.

This edition keeps up the standard to which Dr. Conn and his associates have aspired from the beginning. There is a full list of the normal laboratory values of each subject and a good index. The publishing is as good as ever.

A book of this kind cannot be "reviewed" in the ordinary sense. One can only ask the questions: is its object a sensible one: does it achieve its object? To these one feels that the answer is "Yes."

TREVOR OWEN, M. D.,
Toronto, Canada

ATYPISCHE PSYCHOSEN. By *Bernhard Pauleikhoff*. Basel (Switzerland) and New York: S. Karger, 1957. pp. 141. Fasc. 99 of *Bibliotheca Psychiatrica et Neurologica*.

The author is interested in the presence or absence of a meaningful order (*Sinngesetzlichkeit*) and, or, of meaningful relationships (*sinngestzliche Zusammenhaenge*) in experiencing. He is of the opinion that it depends essentially on 3 factors whether and how far the experiential structure of a personality is meaningful, namely on 1) constitutional factors, 2) the age, 3) the past experiencing and 4) on the situation. He attempts to show that the meaningful order is important in differential diagnosis. He illustrates his thesis with 14 histories of atypical cases, the differential diag-

noses between psychopathy and (schizophrenic) psychosis; between psychosis on a physical basis (brain tumors) and schizophrenic or manic-depressive (cyclothymic) disorders; between atypical psychotic pictures and possible brain changes. He adds cases in which the distinction between schizophrenic and cyclothymic psychosis is not safe. The author warns that the individual "cannot determine the situation completely, but has to adjust himself within limits to the situation." He assumes that the meaningful order in perception and thought is often disturbed in schizophrenia. In uncomplicated cyclothymic depressions, the meaningful relationship to the (structure of) the personality may be disturbed; delusions of guilt, impoverishment, hypochondriasis fit in meaningfully. Certain paranoid delusions (persecution) may make the differential diagnosis difficult or even impossible at least in cross-sections.

This is a very scrupulous piece of work in which the author used several statistical figures from material of the psychiatric-neurological clinic Heidelberg. He follows in most regards his teacher Kurt Schneider to whom the book is dedicated. It is not always easy to follow the author's trend of thought as he seems to have a certain predilection for complex formulations and complex words. This review might appear to him a not permissible simplification of his discussion. However, it is not so much what he expounds as the way in which he does it that lends a certain originality to his presentation. Nobody will deny that the "Sinnzusammenhang" can be a most helpful tool.

Dr. Pauleikhoff's review of the pertinent literature with which he begins his book is the more commendable as this is his first sentence: "The importance of Emil Kraepelin for psychiatry can scarcely be overestimated." (Die Bedeutung Emil Kraepelins fuer die Psychiatrie kann schwerlich ueberschaetzt werden.)

Houston, Tex.

EXPLORATIONS IN AWARENESS. By J. Samuel Bois,
(New York: Harper and Brothers, 1957, pp.
334. \$2.75.)

The author who is an important Canadian industrial psychologist and Past President of the Canadian Psychological Association has applied the theories of Alfred Korzybski to problems of business management. This little book represents many years experience and of course will prove useful, not only in executive training, but also for anybody who has to work with people, (and who doesn't?).

His format is much more easily followed than Korzybski's original *Science and Sanity* and the popular, frequently humorous, approach may well shock some of the stuffer 'disciples' of General Semantics. Its readability has however not detracted from the basic scientific thinking and the original ideas for application of the author. He carefully takes us through problems of verbal confusion, winding up with a program for guided awareness and methods of thinking and speaking

more precisely—hence more lucidly. He has a final chapter comparing danger indicators of what we say, what we do, how we say it and how we do it, which should prove useful in helping us, as the author puts it, to 1) "stop wearing ourselves out or destroying ourselves by excessive bursts of energy; 2) keep functioning within an optimum range of efficiency; 3) adapt ourselves to shifting objectives and changing conditions."

If you are familiar with General Semantics this text will give you a different viewpoint. If you do not know Korzybski's work, this text is an exciting beginning.

DOUGLAS M. KELLEY, M.D.,
Berkeley, California.

UNDERSTANDING HUMAN BEHAVIOR. By James L. McCartney, M.D. (New York: Vantage Press, 1956. \$3.50.)

The author states his goals as follows: "This book is an attempt to bring together what is known about human behavior and what can be done to help maladjusted individuals gain a healthier state of mind."

A little less than the first half of this 258-page volume is devoted to the normal personality and its various functions. The first chapter is on the integrated personality followed by 3 on frustration, guilt and dreams. His approach is multidimensional as he discusses heredity, congenital defects, the central nervous system, the endocrines, nutrition and psychological influences. The latter follows current genetic and dynamic concepts.

The remainder of the book is largely devoted to personality problems and their treatment. One chapter on diagnosis reproduces The American Psychiatric Association's standard nomenclature in full and gives percentages seen in hospital and private practice, as well as a discussion of the main diagnostic categories. The next chapter considers normal and aberrant sexual behavior. Therapy is discussed in chapters devoted to individual and group psychotherapy and to physical therapy. Dr. McCartney closes his book with a discourse on a philosophy for life. Throughout, he gives a large number of case illustrations which are refreshing in their brevity although occasionally they are so condensed as to be emasculated. A glossary of technical terms makes this book more useful to the average reader.

One can find fault with a number of details: intelligence is considered to be rigidly fixed at birth; the discussion of 47 instincts and their corresponding emotions; fear is the only perception in early life; bowel training is to be started at 6 months; the definition of transference as having confidence in the therapist, and the importance of the death instinct, etc. In its comprehensiveness, coverage often had to be superficial in certain areas, but a great amount of pertinent material has been brought together in a cohesive fashion.

On the whole, this book is a sound one and may safely be recommended to public libraries for the use of interested laymen.

Cornell University Medical College.

PSYCHIATRIC FACILITIES IN PRISONS AND CORRECTIONAL INSTITUTIONS IN THE UNITED STATES

WARREN S. WILLE, M.D.¹

The following report is based on a questionnaire survey of prisons and correctional institutions in the United States which was carried out in July, 1954. Because of the dearth of information on this subject, it was felt that such a survey was long overdue. The subject was discussed with Dr. Winfred Overholser at the May, 1954 meeting of The American Psychiatric Association in St. Louis, and it was decided that a comprehensive survey would be made of psychiatric facilities in penal and correctional institutions for the care of young adult and adult offenders. This was in keeping with the present intention of The American Psychiatric Association to make a thorough survey of all facilities in the United States for the treatment of mental illness. It was felt that a similar survey of institutions for the care of juveniles was equally important, but this was considered outside the scope of the present project. Since most of the juvenile institutions are under jurisdictions completely separate from more of the state institutions for adult offenders, a survey of the juvenile institutions would necessitate a separate study.

When this research project was planned in the early part of 1954, the only previous survey with which to make any comparisons was the one carried out by Dr. Overholser in 1926(1).

In the early part of 1926 the National Crime Commission through its subcommittee on the Medical Aspects of Crime, took steps to ascertain the extent to which psychiatry was employed in the courts of criminal jurisdiction and the penal and correctional institutions in the United States. The questionnaire survey of these institutions was completed by July 1, 1927. This original survey included all juvenile institutions as well as the state prisons, farms, jails, and the various criminal courts. At that time it was interesting to note that in the various state prisons, reformatories, and farms there

were only 19 full-time psychiatrists and 24 part-time psychiatrists employed. Twenty-four of the states had no psychiatrists, either on a full or part time basis, and 34 prisons had no psychiatrists in their employment. At that same time the federal prisons reported only 3 full-time psychiatrists and one part-time psychiatrist. This certainly reflects the enormous neglect of the personal study of offenders at that time.

Soon after the writer sent out the questionnaires in the present study, it was learned through the June 1954 issue of "Correctional Research"(2), that the United Prison Association of Massachusetts had just concluded a survey of the 48 states. Their survey consisted of a brief questionnaire directed to the departments of correction of the various states, in which the following question was asked: "Does your state provide psychiatric services for inmates in any of its correctional institutions for adults?" (Other than institutions for criminal insane or defectives).

Because this previous questionnaire was directed to the departments of corrections of the various states, instead of to the individual institutions, it was felt that the present questionnaire study should contribute some further information on this subject. In the present study, a 3-page questionnaire containing 39 items was mailed to all 315 state and federal correctional institutions listed in the directory of state and national institutions published by the American Prison Association. Of the 315 institutions so listed, 167 were prisons or reformatories for adult or young adult offenders. The remaining 148 were camps, prison farms, ranches, industrial schools, or state training schools for juveniles which happen to be under the jurisdiction of departments of correction. One institution listed in the directory was a state hospital for the criminally insane and 3 were special institutions for defective delinquents. Since the names of the institutions did not always give a clear indication of the nature of the facility,

¹ Director, psychiatric clinic, State Prison of Southern Michigan, Jackson, Mich.

questionnaires were sent to all 315 institutions in the directory.

A total of 171 completed questionnaires were returned. Fifty of these had to be discarded for the purpose of this survey because they were from institutions for juvenile offenders. The remaining 121 questionnaires were received from the 167 prisons and reformatories listed in the directory, for a total response of 72%. No returns were received from the farms, forestry camps, cattle ranches, and other small units. This might be expected since it is known that the majority of these units do not have any psychiatric treatment facilities.

The state and federal systems will be discussed separately, because the 17 adult institutions in the federal system generally have much more adequate psychiatric staffing than the state systems. (See Table A.) Of the 104 state prisons and reformatories reporting out of a total group of 150, 80 stated that the services of a psychiatrist were available within the institution. Only 19 reported having the services of a full-time psychiatrist. Twenty-eight had psychiatrists working regularly, but on less than a full-time basis. Thirty-six had psychiatrists employed in a consultant capacity only.

In the case of those institutions having a psychiatrist working on a consultation basis, the question was asked as to the approximate number of visits to the prison a year. Fifteen institutions reported only 2 to 12 visits per year. It was felt that for practical purposes these institutions have nothing in the way of psychiatric services. Nineteen institutions reported 13 to 50 visits per year. Nine reported that their consultants made more than 50 visits per year.

Most of the psychiatric services were concentrated in a few large institutions. Several of the 19 institutions having full-time psychiatrists also employed one or more part time psychiatrists or psychiatric consultants.

Ten states reported that they had no psychiatrists working in their correctional institutions, even in the capacity of consultants. Thirteen other states plus the District of Columbia and the Territory of Hawaii reported that they had no psychiatric services in their adult correctional institutions except for psychiatrists making occasional visits in a consultant capacity. This gave a

total of 23 states, plus the District of Columbia and the Territory of Hawaii, which had no psychiatric facilities in their correctional institutions, or else had no services except for occasional visits by psychiatric consultants.

At the time of this survey, the 80 state institutions reported a total of 31 full-time psychiatrists, 34 part-time psychiatrists, and 42 psychiatric consultants, for a total of 107 psychiatrists working in state adult correctional institutions.

The Federal Bureau of Prisons had much more adequate coverage, in that there was some sort of psychiatric service available to all 17 of the federal adult institutions. The federal system employed 12 full-time psychiatrists, 5 part-time psychiatrists, and 9 psychiatric consultants in their 17 institutions. However, even in the federal system, a widespread lack of adequate psychiatric facilities was recognized. Dr. H. M. Janney(3), Medical Director of the Bureau of Prisons, has commented on his difficulty in getting psychiatrists to fill vacancies in the federal penal system.

Combining the figures for both state and federal systems, there is reported a total of 43 psychiatrists working full-time, 39 on a part-time basis, and 51 in a consultant capacity only. This gave an overall total of only 133 psychiatrists in the U.S.A. who spend any time working in our state and federal penal institutions. (Table B.) There was close agreement between these results and the findings of the previous survey independently conducted by the United Prison Association of Massachusetts, which reported at total of 128 psychiatrists working in prisons (*ibid.*).

Those states having no psychiatric facilities in their prisons usually transfer the obviously psychotic inmates to one of the state mental hospitals. However, the lack of any professional staff within the institutions to evaluate the mental status of prisoners or to make judgments as to which ones are in need of psychiatric treatment, means that there must be many psychotic inmates within correctional institutions who are either not recognized as such, or who are not given adequate treatment. This is evidenced by a comment made in one of the questionnaires to the effect that a particular mid-western

institution had a 75-bed psychiatric ward, but there was no psychiatrist working in the institution. This same institution reported that patients in the mental ward were examined once a year by a state hospital psychiatrist!

The situation is not quite as bad as it first appears from examination of the questionnaire returns. In several states, machinery exists for psychiatric evaluation of mentally disturbed inmates in regional mental health outpatient clinics. Two institutions in Iowa have such an arrangement, as does the women's prison in Connecticut.

At the time of this survey, several states which did not previously have satisfactory facilities were rapidly developing an improved program. For example, Mr. Harold Donnell(4), Superintendent of Prisons of the State of Maryland, reported that in October, 1954, Maryland was opening the Patuxent institution to serve as a diagnostic center, psychothpathic unit, and defective delinquency unit. The entire psychiatric staff would be available for work in all the other institutions under the Department of Corrections. This would be similar to the systems adopted in the States of Wisconsin and New Jersey where a central agency furnishes psychiatric services to all the penal institutions in the state.

California, which already was one of the leaders in the use of psychiatric personnel in state penal institutions, was at the time of this study rapidly enlarging professional services for the youth division and had

started an inservice training program for all employees. California has also built reception guidance centers for initial diagnostic studies on all incoming inmates, both for the adult and youth divisions.

An attempt was made to find out the quality of professional staff and adequacy of their training by asking the various institutions whether or not the psychiatrists they employed were certified by the American Board of Psychiatry, or board eligible. Of the 130 psychiatrists reported to be working in our prisons, 53 were reported to be board certified and 27 to be board eligible, for a total of 80 so qualified. However, the number may be slightly higher because a few of the institutions hiring psychiatrists failed to complete this item on the questionnaire.

Only 6 institutions (the State Prison of Southern Michigan, Sing Sing Prison, Massachusetts Reformatory for Women, Connecticut State Prison, San Quentin Prison, and the California Medical Facility at San Pedro) reported that they were utilizing psychiatric residents in their prison programs through arrangements with nearby medical schools. It is felt that there is a widespread lack in the training of psychiatric residents in forensic psychiatry. Many of the major prisons are located near medical centers and arrangements could be easily worked out for psychiatric residents to spend some time in the psychiatric clinics of our prisons and reformatories. All of the psychiatric residents I have talked with who have worked in prisons feel it has been a very worthwhile experience. However, before more residents are utilized in our prison programs, obstacles in two different areas will have to be overcome. First, the various states will have to provide funds for adequate salaries for board certified psychiatrists to work in the prison hospitals, so that there will be sufficient well qualified persons to supervise the residents. Secondly, more medical schools will have to take the initiative in working with the various state corrections departments to set up adequate training programs.

An attempt was made to find out how much individual and group therapy was being carried on. Seventeen institutions reported that they had a sufficiently adequate staff to

carry on individual psychotherapy with at least a few inmates. Twenty-eight of the institutions had group psychotherapy classes. In the remainder, the staff was so limited that the psychiatrist's time was used almost entirely for handling psychiatric emergencies, or else was spent with so many routine duties that no time was left for individual or group psychotherapy. Several institutions utilizing group psychotherapy were quite enthusiastic about it and felt that they were able to make the maximum use of their limited staffs by employing group therapy methods.

Forty-seven prisons reported that they had psychiatric wards within their own hospitals. These ranged in size from small segregation units of 3 beds up to wards of 120 beds. The majority of these were small units, with only 10 institutions reporting psychiatric wards of over 25 bed capacity. The various prisons reported a total of 1,356 psychiatric beds. Institutions for the criminally insane were deleted from this survey so this number represents psychiatric beds in excess of those provided in separate institutions for the criminally insane.

The quality of psychiatric care given in most of the prison psychiatric units is usually far below the standards recommended by The American Psychiatric Association. Eleven of the units with psychiatric wards reported that they had no trained civilians looking after the patients and that this work was done entirely by inmate attendants. Nineteen units reported that they had inmate attendants under the supervision of one or more trained civilian attendants or nurse supervisors. Only 10 units had the entire nursing staff composed of civilians.

Only 31 institutions reported that they had psychiatric reference libraries, and 28 kept diagnostic files on all of their patients according to the procedure recommended by the committee on nomenclature and statistics of The American Psychiatric Association.

Institutions were asked to name any psychological tests or methods which were employed in an attempt to measure all of the most important components of their treatment programs. Tables A and B. C. Ninety psychologists were reported to be working in prisons, an average of less than 2 for each

state in the Union. Eighty-five were reported for the various state prisons and only 5 in federal employment, showing a severe shortage of this particular professional group in the federal system. It is not known whether all of these possessed sufficient qualifications to correctly use this title. In a previous survey of psychologists in prisons in 1932(5) there were 60 psychologists known to be operating in adult correctional institutions. Of this group only 39 were American Psychological Association members.

Ninety-eight social workers were reported to be working in the various state adult institutions and 66 in the federal prisons. Here again it is not known how many of these were adequately qualified by training and experience to properly use this title. Only 34 of the 58 adult correctional institutions hiring social workers reported that they used the "teamwork" type of clinical approach in their program.

Only 8 penal institutions indicated that they had electroencephalographic laboratories. A number of other states made frequent use of the EEG facilities of nearby state hospitals. However, the number of inmates who would have EEG studies as part of their clinical examination would certainly be much less in any institution which had to send the inmate to another facility for such a study. In such cases, these studies would undoubtedly be carried out only in those situations where the person was thought quite definitely to have some sort of neurological disorder.

Eighteen state institutions and one federal adult correctional institution reported that they were carrying on research projects. The paucity of research in the correctional field is due to the chronic shortage of trained clinical personnel. Most of those employed in corrections work have been so busy with urgent immediate problems that they have had no time whatsoever for research. This picture can improve only when more professional persons go into corrections work and individual caseloads are relieved to the extent that not all time is spent in dealing with day to day emergencies or routine administrative work.

With the guarantee of anonymity of the institution and the reporter, the person com-

pleting the questionnaire was asked to indicate whether there were persistent areas of discord with custodial personnel. The majority of institutions with psychiatric facilities answered in the negative. However, the following comments were received:

"The custodial personnel think that working around a person and reasoning with those who have a mental quirk is pampering them—that the minute you say something they should jump and do it—it is most difficult to make the older employees see that you have to work around that type of person."

"Tend to use and want to use psychiatric ward as punishment or to handle disciplinary problems rather than psychiatric cases."

"There are some problems which may be subsumed under the traditional conflict between philosophies of punishment and those of treatment."

"Security more basic to institution than therapy."

An excellent example of the problems encountered when a therapeutic program is first started in an institution where custody has previously been the main orientation, is given in a recent article by Dr. Norman Graff(6). In this he writes up his interesting personal experiences when he began working for the first time in a prison hospital, and met resistances of this sort.

A somewhat similar development took place in the State Prison of Southern Michigan, where a psychiatric treatment program was generally unknown to the custodial personnel prior to 1953. As the program developed, more and more custodial officers developed some interest and understanding of the problem of mental illness in prisoners. Now regular training meetings take place with representatives of custody sitting in on weekly staff meetings in the psychiatric clinic, and with members of the psychiatric clinic sitting in on some of the meetings held by custody for the disposition of inmates' problems.

The problem is by no means unresolvable. In those institutions where there has been an inservice training program with frequent meetings between psychiatric and custodial personnel, these difficulties can be largely overcome. Such meetings allow for a common understanding of objectives and methods and help to break down the misunderstandings about psychiatric treatment that usually exist in custodial personnel who have never previously worked in a therapeutic program.

It is felt by the writer that inservice training programs and group discussions are

essential in overcoming the mistrust of therapeutic techniques where the milieu has previously consisted only of confinement and punishment. Graff(6) also remarked that he felt that the therapeutic program of any prison psychiatric unit stands or falls on the relationship which develops between the psychiatrist in charge of the unit and the officers who translate his ideas into action.

The various institutions were questioned as to whether there was an organized program for training of other civilian personnel in the fundamentals of mental hygiene. Only 23 institutions reported that they had included this in their inservice training program, and these were generally in the prisons with the more adequate psychiatric facilities (part-time or full time psychiatrist).

Many interesting general comments were received with the questionnaires. The majority of institutions felt a dire need for additional psychiatric facilities as judged from the following remarks:

"We need a full time psychiatrist and social worker here and we are trying to get our legislature to set up these positions."

"At this institution we have no provisions whatsoever for mentally disturbed inmates. Neither do we have the facilities in our hospital for handling that type of inmate. In my opinion, it is one of the things seriously lacking in this institution. All our nurses at this institution are inmates trained by our medical staff and are not trained in psychiatric work."

"We're always short of staff to reach effectively all those who need therapy."

From one mid-western state well known for political domination of its state institutions:

"Our trouble is administrative. We have had 6 superintendents in less than 2 years. Basically the evil is political domination and manipulation . . . far too much stress is placed on custody and the physical plant. We are grossly inadequate with regard to professionals and trained personnel."

"We have been handicapped by the scarcity of psychiatrists in this region and it has been impossible to get more than the barest minimum of psychiatric evaluation and consultation on our most seriously disturbed cases. The psychiatrist at the local guidance center is in town only 2 days a week and by necessity must give most of his time to the mental hygiene clinic, since that is the job for which he is hired. Although we feel fortunate in having the facilities of one of our state mental institutions in the immediate locality, that institution is understaffed and has only one psychiatrist for the entire female population of the hospital. These are the only 2 psychiatrists in town that can offer us any time whatsoever. It is the hope of our State Department of Institutions to be able to hire a psychiatrist

1957]

who will be able to visit each of the correctional institutions in the state for several days out of each month. However, this still remains a hope that has been as yet unrealized."

Certainly part of the difficulty lies in the continuing shortage of psychiatrists and the inability of some institutions to hire trained personnel even when the legislatures have made appropriations for such positions. For example,

"At the present time, we have no psychiatrist on the staff here at the penitentiary. Certainly, we have quite a number of inmates who would be benefited by the services of a resident psychiatrist. However, up to this time, we have been unable to employ one."

Although this survey was limited to the adult institutions, some of the comments from the institutions for juvenile delinquents revealed the problem there to be equally pressing:

"We do not take mental defectives or badly disturbed children if we can help it, but the last year we have had plenty of them. We would like very much, if we have to run an institution for mentally ill children, to have a full time psychiatrist. This should be one or the other institution—a training school or a mental hospital, but not both!"

"We find that as welfare services in our state have increased and more services to children are available in the communities where youngsters live, there has been a screening process going on whereby the milder delinquents that we used to receive are not now being committed to the training school—because their problems apparently can be successfully handled by the newly developed services in the various communities. Although we think this is very fine it does present a problem, inasmuch as the complexion of our population has changed almost entirely in terms of the severity of problems presented by boys as they enrolled. We feel that we are now receiving boys who present emotional and mental abnormalities in large numbers, to the extent that these abnormalities are socially disabling. We also receive some children who are psychotic, others who might be termed pre-psychotic, and we do not feel that a training program alone can meet the needs of the youngsters we are called up to care for. Hence our decision to seek a psychiatric unit and to add all the auxiliary services usually required."

SUMMARY

On the basis of this survey in 1954, only 43 psychiatrists were working full-time and 39 part-time in the 167 prisons and reformatories of the United States and possessions. In addition to this small group, there were 51 working in a consultant capacity. How-

ever, some of these rendered only token services to the prisons by making visits less frequently than once a month. Twenty-four states plus the Territory of Hawaii had no psychiatric facilities in their prisons, or else had no services except for occasional visits by psychiatric consultants.

It is obvious that the psychiatric study of the criminal offender is still a largely neglected field. Despite the increasing recognition that many repetitive offenders are mentally ill and that criminal behavior stems from unconscious conflicts, very few criminals actually receive thorough psychiatric study or treatment. The level of care rendered to the mentally ill person in the prisons of many states is still at no higher a level than was common in the average asylum of 100 years ago. From the humanitarian standpoint alone, the level of care provided to the mentally ill in prison should be made to approximate that given in the average state hospital. There is no less a need for additional research in this field, inasmuch as the average state now has to allow as much in its budget for the care of criminal offenders as for the maintenance of its mental institutions.

Settle(7) feels that the best way to better treatment for the abnormal offender is through the expansion of psychiatric services in the correctional system rather than through changing concepts of criminal responsibility. This is the most that can be hoped for at present, since it will certainly be some time before there is any widespread change in the concept of criminal responsibility which would permit a sizeable proportion of such offenders to be screened out in the courts and sent to hospitals for psychiatric treatment(7, 8).

OBSERVATIONS ON THE THERAPEUTIC ASPECTS OF ADMINISTRATION IN PUBLIC MENTAL HOSPITALS¹

WALTER E. BARTON, M.D.²

CHARTING A COURSE

How can time possibly be found in a state mental hospital for psychotherapy? There are so many patients to be cared for that it is difficult to find time even for essentials; an hour spent with a single patient is a luxury seldom possible. The urgency of demands for service is indeed very great. The admission of patients, their examination and work-up, the development of a treatment plan, diagnostic and service staff meetings are all very time consuming as is the actual application of such treatment as electric shock, insulin, etc. Ward rounds also are time consuming, especially if there are few doctors and many wards and patients. There are assignments to be made of patients to activities, permissions to be granted, and a hundred and one administrative tasks to perform. Visitors and relatives also demand to be seen. There just isn't enough time in the day.

There is time for what is really important. But what is important? For some, the appearance of wards will be; for others, the nursing care given to patients; and perhaps for still others, the amount and extent of therapy that can be given. All are important, of course, but if a choice must be made within available resources, perhaps therapy deserves the greatest emphasis. It is certain that what the administrator feels is important will influence those about him and help certain things to get done. If therapy is a major goal of the administrator this will be known. If he regards psychotherapy as an extravagant waste of time, impossible in the setting of a state mental hospital, it will not be done.

² Superintendent, Boston State Hospital, Boston, Mass.

GETTING PEOPLE TO WORK TOGETHER

There are many different forms of hospital organization and different ways in which administrators get policy into action. For example: having decided that it was a good idea to have "psychotherapy," the administrator might issue an order that all doctors will spend an hour a day with a patient in individual therapy and an hour a day with several patients in group therapy. A better approach would be for the administrator to explore together with physicians their convictions as to the relative importance of psychotherapy in the treatment of the psychotic patient. A demonstration project might be set up utilizing those doctors who are most sympathetic to the point of view selected for the demonstration. Progress of the patients in therapy should be "fed back" to the group and encouragement given to others to share in the work. Provision should be made for supervision and guidance of the psychotherapists by more experienced men.

The administrator need not retain active direction of the project. This can be delegated to the clinical director or to qualified chiefs-of-service. It is important when delegating responsibility that the necessary authority be given to accomplish the objectives. Over-ruling and under-cutting are extreme hazards and may nullify any program. The administrator must be very careful to resist the temptation to make decisions that should properly belong to others. His support of those who carry the responsibility is an absolute requirement.

Let us consider a few examples of stress: a patient in psychotherapy may become destructive. An order might be issued to restrain the patient, or the administrator might rather express his concern over the patient's disturbance to the administrative physician and let him in turn discuss it with the patient's therapist as a reality problem to be dealt with in therapy. Electric shock, chemo-

therapy or deprivation of privileges may be employed when crises occur. Demands that they be used in place of psychotherapy, or in addition to it, may make the therapist believe the administration actually does not trust psychotherapy or believe in it.

Sometimes, however, authority can be a useful tool in the treatment process. A patient may often be helped by setting limits that clearly show that his behavior and conduct are socially unacceptable or that certain things must be done in the hospital setting for the well being of the whole group.

PRESSURE FOR CERTAIN TREATMENTS

Today, nearly everyone is interested in psychiatry. The mass media contain many references to the treatment of mental illness. Popular magazines and women's journals tell of successful treatment of mental disorders. People as a consequence, demand that their relative have the kind of treatment they have read about.

Usually the treatments extolled are those somatic therapies that express the elusive hope that a brain operation may cut out mental illness or a pill may give courage to meet stress and overcome frustrations. Furthermore, relatives see John Doe recover from shock treatment. They request, with a great deal of pressure, that their relative also have it. Psychotherapy, oftentimes, is disregarded as effective treatment because "talk doesn't count." It is not uncommon for the patient and the relative to feel that "nothing is being done for him" when only an hour a day is spent in "conversation."

Patients in psychotherapy may experience an increase of anxiety or may express their hostility, not only to the therapist but also to relatives. When a patient has been quiet, regressed and chronically ill, this may prove alarming to the family. They beg that psychotherapy be stopped because "it is making him worse." Oftentimes, dissatisfied with the explanation of the physician, they may go directly to politicians or to the Department of Mental Health and demand that the patient be transferred or be left peacefully alone. Doctors make a mistake, however, in interpreting inquiries on the part of politicians or mental health authorities as being

critical of the treatment or demanding change. Usually the governmental official wants a prompt, clearly stated answer that he can understand and believe, that will satisfy the constituent who is putting pressure on him. Almost always, service to the public official, promptly given by the doctor, will gain an ally that will support rather than hinder his work. It is important for the administrator to permit the physician to direct the medical treatment of his patient and to give him the needed support.

One of the functions of the administrator is that of facilitation. He must remove the "road blocks" and frustrations that interfere with getting a job done and do everything possible to make it easier for the therapists to function comfortably at their work.

Resistance to psychotherapy sometimes develops within doctors themselves. Sitting in intimate daily contact with psychotic patients may arouse their own anxiety. Protests against the pressure of paper work, or being tied to a desk by administrative details, may often be the projected expression of a desire to escape the anxiety evoking therapy hour. The administrator, being aware of this, can encourage a realistic approach toward working through problems with the supervisor of psychotherapy. Competent supervision is most important for those who are doing intensive therapy.

The personality of the one in authority influences the organization as much as does his interest. It determines the way in which the administrator functions and how he meets his own needs. He has many roles to play: clinical psychiatrist, consultant, leader in the hospital and in the community, husband and father. In the hospital he listens to a department head bemoan the fact that a cook has been caught walking out with a ham, or to a relative complaining about a patient's lost glasses. He reads a doctor's memo about a patient who remarked in group therapy that an aide abused him or reads a report from the chief nurse that some man was in the nurses' quarters after hours. While he is doing this, he has answered a telephone request to authorize the retention in the hospital of a patient from out of district or a request to speak to a volunteer group. While he talks on the

place he runs the mountain of correspondence reports, and forms, and after stuffing all letters, over one page long, in his brief case along with reports and journals, he runs the gauntlet of "corridor conference" requests.

Executives in industry have found the psychiatrist may meet his need for help with personal problems or for the opportunity to clarify business problems. The "lonely" executive has no one to whom he can ventilate his problems. The mental hospital administrator could well "take some of his own medicine." It may help to consult with a psychiatrist in the community, (who is not a member of the staff) about his own problems. What he expects from life, what share of it shall be his family's, and what acceptable ways he may need to release tension are legitimate areas for help. Greater use could also be made of consultants who are experts in the various fields of administration.

There is an obligation upon the therapist for an evaluation of the results of his intensive work with the psychotic patient. Does psychotherapy do any real good? The therapist may be the only one who believes the patient has changed for the better. It may be helpful to learn what others think, by eliciting the opinions of ward personnel and patients through interviews or questionnaires. A rating may serve to objectify change. It is interesting that when psychotherapy is one of the basic instruments of treatment, the patient often feels that he knows his doctor, that there is someone who cares, someone who has patience enough to be with him day after day. He frequently leaves the hospital with a very warm feeling that something *has* been done for him.

Clinical reports, careful research analysis, or administrative measures to determine the number of patients who have gone to better wards, who have been occupied in activity programs, or have become less destructive, or left the hospital and gone into the community, may be of value in making a determination whether or not a particular kind of treatment is helpful. The administrator can encourage such evaluations in medical departments, just as in the business departments. It is always well to make a medical

audit(1) to see if one is using one's resources to the maximum benefit of all concerned. Evaluation of results may lead to the wisest use of limited resources, and there is nothing more limited than the physician's time.

ADMINISTRATIVE ORGANIZATION FOR EFFECTIVE FUNCTIONING

In using the analogy of psychotherapy as an expression of administrative philosophy, we have tried to show that this becomes a determinant of administrative policy. Effective functioning of an administrative organization depends on more than articulate policy. It depends on the interrelationships within the determined program between personnel needed and available and the necessary financial support to supply the needed tools and facilities.

Any program begins with clearly defined objectives that are the expression of the administrator's purpose. The good mental hospital is the one whose purposes clearly give priority to therapy and rehabilitation of patients, and have as associated goals, the training of all personnel. The good mental hospital will also encourage research interests. Not many mental hospitals, as they are presently staffed, will be able to undertake elaborate scientific studies, but most will be able to do clinical investigations and evaluations of services.

The planning for an administrative program is best explored in a "grass roots" conference involving the action personnel. This is far more time consuming than the promulgation of a prepared plan. When suggestions for solutions of problems come from the group affected and when that group shares in the development of the plan and the policy, there is more willingness to work constructively toward the goal. It is helpful, therefore, to organize a working committee of representatives of the particular group affected by any procedure. It is disturbing to morale to invite workers to conferences where it is evident that their ideas and thoughts are not heeded or wanted. Their suggestions are solicited, listened to, and distilled into a plan submitted to department heads or to an executive council. After discussion at this level, the amended plan is

again circulated as a policy draft to see if statements made represent what participants thought they said. When it meets the approval of the majority of the action persons, it is published as policy. This does not end the procedure, for at this point careful follow-up is required to translate paper plans into patterns of behavior and into an administrative program.

Any plan made must be studied for its effectiveness in operation. This may be done in a number of ways. The leader may visit and talk to patients and employees, manifesting an interest in their problems and invite their suggestions for improvement of operation or criticism of the procedure as presently carried out. It is possible also to sample its effectiveness through the construction of some measuring device, a time study, the number of man-hours it takes to do the job, the use of a questionnaire, the study of its functioning by a sociologist, or by the securing of the opinion of a group affected by the program.

LONG RANGE PLANNING

Planning begins with the simple assessment of how the job can best be done with the means at hand. The study of the problem includes an analysis of possible solutions and their consequences. Next, one determines what is most needed to do the job better, and lastly how the job could best be done if all needs were met and resources supplied. For new and radical approaches, it may be well to assemble a "board of dreamers" and encourage them to speak freely of even their "wildest" solutions. Some of the long range plans that have emerged demonstrate how administrative planning can actively affect the therapeutic program.

1. It is suggested that an attempt be made to expand the family doctor's knowledge of psychiatry and competence in dealing with psychiatric disorders so that he may be able to abort crises and give the patient enough support to manage his own problems.

2. The Boston State Hospital will explore the feasibility of a home-care plan for patients with an acute psychiatric illness. It has been learned that a certain proportion of admissions are referred from home when a critical point is reached in the relationships

between members of the family. Perhaps a psychiatrist and a social worker going to that home can give sufficient supportive services to maintain the patient.

3. Outpatient and aftercare clinics can be expanded to meet needs only if there are more therapists available. Perhaps it will be possible to utilize time of staff physicians more in this part of the program, if home care plans and other preventive programs reduce admission pressure somewhat. Part time physicians can also be of service at this point to increase outpatient resources.

4. Intensive treatment for those requiring inpatient care can be given more promptly. There is often a period of observation and delay in the application of individual treatment. Every new patient requires immediate intensive study and symptomatic treatment to relieve suffering and potential disturbance. It is felt highly desirable also to involve the family as early as possible after the patient is admitted. Perhaps it would be helpful to invite the family to participate in the active care of the patient on the ward so that they may learn from association with other relatives and with staff what actually goes on within the hospital setting. Instead of bridging the gap between the hospital and the community, an attempt is thus made to keep the gap from occurring.

5. Patients can share more in the responsibility for their own treatment and can plan their own participation in the program. There has been an active interest in the development of patient government, of patient groups, and of patient committees that give them a voice in planning.

6. The staff also needs an opportunity to form close interpersonal relationships with a few patients. If small groups of patients have close contact with staff, there is often open expression of hostility, seductive behavior, or anxiety. Close contact brings problems to the surface where they can be more effectively dealt with. This requires more support of action personnel by experienced supervisors in order to deal with the therapists' personal anxieties(2).

One project of this type at the Boston State Hospital is known locally as "The Forward Look." Formerly when patients had become quiet and cooperative, they were

given responsibility for self care; one attendant was available on one shift of the day for 100 patients in an open building. However, it was learned at the critical point of convalescent status the patient needs more active staff support to continue the forward movement toward return to the community. Ten patient groups of 10 each were formed with an aide, nurse, or other staff person designated as the group leader, who met with the group regularly at least once a week. The releases from the ward doubled as a result. It was necessary also to provide a group leaders' meeting in order that support could be given to the aids and nurses working closely with patients.

7. Early release of patients is facilitated after a chronic mental illness through the provision of support during the period of transition from hospital to community. Sometimes the night plan is effective. The patient goes to work during the daytime and returns to the hospital at night. Oftentimes the patient may be ready to work in the community long before he can face the prospect of living in stressful home situation surcharged with the emotions of unresolved conflict; or he may be without resources. To abandon him to a lonely room would be the worst possible therapy. A halfway house, a family care home, or a "day hospital" plan may be the solution.

8. At some point in the development of the patient's treatment, vocational guidance plays an important role as he begins to think about the actual work he will undertake. At this point, hospital industrial placements often fail to actually prepare patients for work in the community. Intensive job training may be needed to develop work habits

at a level acceptable in the community. His habits of personal cleanliness become a concern as does his punctuality in reporting for work. Steadiness and dependability are needed and the capacity to work a full 8-hour day. In the atmosphere of support within the group, and with good supervision, the patient is able to accept constructive criticism more readily, and to dare to try out new patterns of behavior which he learns through repetition.

9. After the patient returns to the community there is need for follow-up supervision. The mental hospital doesn't deal only with the needs of its patients but also with the attitudes of family and of employers and other problems of adjustment in the community. The support of the social worker or his therapist, or of his group in therapy, or of a patient social club may be needed to give him confidence to meet these daily problems.

Any administrator who lives in the climate of planning with the responsibility for carrying out any program must look to the future and anticipate changing needs. Into his planning folder go ideas that later become crystallized into administrative decisions that will influence therapy. Administrative philosophy becomes translated into programs of treatment and human relationships are stimulated toward the achievement of the common goal of better patient care.

CONTRIBUTIONS OF SOCIAL SCIENCE TO THE ADMINISTRATIVE PROCESS IN THE MENTAL HOSPITAL¹

MORRIS S. SCHWARTZ, Ph.D.²

In order to establish the context for my remarks about the contributions a social scientist can make to the administrative process in, or to the administrator of, a mental hospital, I would like to start with a brief definition of administration and with an exposition of an assumption.

When I use the term "administrative process" I mean simply the process of exercising authority, making decisions and putting into effect the decisions made in order to achieve a desired goal. In a mental hospital the stated and hoped for goal of the administrative process is the immediate or ultimate elimination or diminution of the patient's mental illness or the improvement of his mental health. In discussing the contributions of social science to this process, my remarks will be oriented toward indicating the ways in which social science might increase the therapeutic effectiveness of the administrative process, or diminish its untherapeutic effects.

There is an assumption behind the thesis that administrative processes can have important therapeutic and untherapeutic effects on patients. Let me make this assumption explicit. I am assuming that for a large majority of patients in mental hospitals, the social environment of which they are a part will play an important, sometimes crucial role in alleviating or improving their mental illness or in reinforcing or worsening it. The administrative process is part of this social environment and helps create the atmosphere in which the patient lives. Thus it affects and influences staff and patients and will have therapeutic, neutral, or untherapeutic consequences for the patient population.

I am maintaining that administration in the mental hospital is not only a process that

requires clinical psychiatric skills, but that it is also a process that requires social science skills. If the mental hospital administrator is to facilitate optimal therapeutic care for patients, he will have to use, directly or indirectly, the concepts, knowledge, and methods of the social sciences.

In what ways then can a social scientist contribute to the administrative process in the mental hospital so as to increase its therapeutic effectiveness?

In general, the social scientist can provide a frame of reference within which to analyze, interpret, and evaluate administrative action; and he can provide a mode of procedure with which to observe and trace the consequences of such action. In this paper, I will elaborate 3 areas in which the social scientist can make his specific contribution. First, I will indicate the kinds of perspectives he can bring to bear on the formal structure of the mental hospital. I will next concern myself with how he might go about analyzing the informal social interaction in the hospital. Finally, I will indicate how the method of participant observation can be used in evaluating the effects of the institutional structure and processes on patient welfare.

Let me start with the formal aspects of the hospital, that is, with the way in which the institution is organized internally, and with its image in, and relations to, the society in general. On the most general level, we might ask: what function does this institution serve for the society and how is it related to the community; what kind of a social system is it; that is, what patterns, orientations, norms and values most regularly characterize it; what are its subparts and how do they interlock and fit together? We can then go on to ask whether this social organization as it is presently constituted actually functions to achieve the ends it has set for itself. For example, we might ask if a large scale social organization with its attendant administrative ma-

¹ Read at the 113th annual meeting of The American Psychiatric Association, Chicago, Ill., May 13-17, 1957.

² Address: 868 Memorial Drive, Cambridge 39, Mass.

chinery: its complex division of labor, its specialization in task performance and its isolation from the community is an appropriate kind of institution within which to treat the mentally ill(1). If one assumes that emotionally sick people need highly individualized and personalized care and treatment, we can then try to delineate ways in which a large state hospital, as a social system, is capable of fulfilling this goal; or, one can ask, how such a hospital might be re-organized so as to more closely approximate the goal of maximizing its therapeutic effects. One advantage of approaching the hospital as a total system, and seeing it as an institution embedded in the community and society, and in terms of its own internal structure and dynamics, is that an administrator can make an important distinction among the problems, difficulties and untherapeutic processes and structures that confront him. He might be able to distinguish between untherapeutic processes which stem primarily from societal limitations placed upon him and the hospital, those difficulties that are intrinsic to the form and social organization of the institution as a whole, and those problems that arise primarily because of the ways sub-parts of the institution are structured, operate, and are related. Having made this kind of differentiation the administrator may be in a better position to realistically assess: 1. the relative control he has over the various aspects of hospital functioning, 2. the limitations that restrict his power to make and effectuate his decisions, 3. the possibilities of introducing successful change into those areas he thinks need to be changed.

Another way in which a social scientist can contribute to the understanding of the formal structure of the mental hospital is by focusing on its goals and purposes(2). The mental hospital like any other complex organization may pursue a variety of goals. By his analysis, the social scientist might distinguish those goals that are manifest, are made explicit, or are verbalized as primary, from those goals that are latent, thought to be secondary or enter into the scene unrecognized.

For example, the goal of the mental hospital is ordinarily stated as the cure or im-

provement of the patient. This goal is even implicit in the term "hospital." Rarely is the goal of the hospital stated to be the storage of people who do not abide by our conventional standards, or to be a place of terminal maintenance for persons who are too old to care for themselves. Identifying and clarifying the variety of goals that actually are being pursued might help the administrator to be more realistic about his institution and the reasons for its moving in seemingly divergent directions.

After identifying some of the different purposes a mental hospital is pursuing, the social scientist might indicate the incompatibility between or conflict in, values. For example, there may be a conflict between the needs of the staff and the needs of patients. Thus, patients may be prevented from using their rooms during the day because it is more convenient for the staff to have patients in full view. Or locking the patient up tight in order to zealously protect society from him, may be incompatible with helping him to believe that you trust him and are interested in his welfare. Or organizing the patient's life via routines, orders, and procedures, and regulating his waking and sleeping hours in order to keep the hospital running efficiently, may be incompatible with giving him the responsibility and opportunity to develop his self-reliance and independence. Recognizing such incompatibilities should help the administrator recognize some of the reasons for his indecision and keep him from being torn in different directions. It might also help him recognize the necessity for developing a hierarchy of values, and for distinguishing and seeing the relations between long-range and immediate ends.

The social scientist can also contribute to the clarification of the relation between means and ends. For example, the means used to distribute patients throughout the hospital, by putting patients together who are like each other, *i.e.*, housing excited combative patients, or depressed suicidal patients together, may only result in frustrating the end of helping these patients reduce or eliminate this unacceptable behavior.

Another way in which the social scientist can contribute to an understanding of the effect of the formal organization on patient

welfare is by focusing on the division of labor in the hospital, and the way in which roles are defined and stratified, *i.e.*, how people with different jobs have different amounts of prestige and power and accumulate differing rewards because of their position in the hospital. This focus might lead to an evaluation of the intended and unintended consequences of the division of labor. For example, it might be important to ask whether the ways in which mental hospital personnel are arranged in hierarchical relations to each other, namely the doctor on top, the nurse below him, and the attendant below her, contributes in part to social distance between staff members and to poor communication between them. We then need to ask if this in turn contributes to avoidance of patients by staff and to poor communication between patients and staff. Such restraint in social relations and inadequate communication among staff might make it difficult for the administrator to get the kinds of information he needs to make appropriate decisions. Another problem is whether a subordinate, subject to the orders of many superiors, for example an aide who takes orders from the doctor, the nurse supervisor, and the charge nurse, may become recurrently confused because of his being subordinate to multiple authorities, and as a consequence contribute to the confusion of patients (3). If the various roles are structured so that they encourage or facilitate resentment and lack of satisfaction among the lower echelon personnel, it will be difficult, if not impossible, for them to provide patients with the kinds of satisfactions they need in order to improve. If the administrator recognizes the importance of the ways in which roles are defined, how they are related to one another and the consequences of such definitions and relationships, he might concern himself with re-defining roles or restructuring hierarchical relations. If, however, he takes these for granted and doesn't conceive of the possibility of changing them, the very persistence of these roles in their present form might make it impossible for him to achieve certain ends.

Finally, in analyzing the formal structure, the social scientist might turn his attention to the assumptions upon which it is based

and upon which the administrator proceeds. Administrative action is not only a function of the seeming demands of an immediate situation, but is also determined in part by the assumptions the administrator is making, the philosophy of treatment he holds, the traditions and ideologies by which he is bound, the theories of human behavior in which he believes, and the norms and values that guide his activities. Usually these determining conditions, especially one's assumptions, are implicit and taken for granted. The function of a social scientist might be to make them explicit, to see how they are structured into the institution, and what their consequences are in concrete action. Let me illustrate. If the administrator assumes that mental illness is essentially like physical illness and that the general hospital should be the model for the mental hospital, he will undertake different acts and make different decisions from those he would make if he assumed that mental illness is essentially a psycho-social disability and that treatment should be patterned on the model of the family. Similarly, if an administrator assumes that schizophrenic patients cannot be expected to recover, he will make decisions different from those he would make if he assumed it is a reversible process.

In addition to analyzing the formal structure of the mental hospital the social scientist can contribute to the administrative process by uncovering the different kinds of patterning the informal structure assumes and by evaluating the consequences of such patterning for patient welfare (4, 5). For example, he might investigate the emergence and disappearance of collective disturbances in the hospital (6, 7); or he might focus on the ways in which low morale becomes structured, how it is maintained in the informal organization, and what the processes are that help to raise it (8). Perhaps more important are the kinds of equilibria that become stabilized in the interaction between staff and patients. There are some types of informal patterns that become stabilized that tend to perpetuate the patient's "sick" behavior. For example, a patient's incontinence or his demanding behavior may be elicited and perpetuated by the kinds of responses he receives from staff, and by the

which their interpersonal relations are patterned (9, 10). Careful analysis of such informal processes arise, the forms through which they pass, the forms they take, and the ways in which they disappear may be of considerable use to the administrator in helping him evaluate how these informal processes might be aborted, used, or re-directed for therapeutic ends.

Finally, the social scientist could help the administrator by providing a procedure for gathering information and data he needs in order to make appropriate decisions. Through the use of participant observation, interviewing, questionnaires and conference discussions, the social scientist can systematically observe and record the formal and informal structures and processes in the mental hospital. He can then provide the administrator with a careful, detailed and intimate study of the institutional processes about which he has to make decisions. On the basis of this detailed information and analysis, the administrator might be in a better position to delineate the vulnerable points at which to intervene, to time his decisions more appropriately, and to work out a form and structure for the process of intervention itself which might have an increased probability of achieving the therapeutic ends he is seeking. When the administrator does intervene, the social scientist can observe how the intervention is instituted, and evaluate its effect on the social structure and on the patient's welfare. He can bring these evaluations to the administrator's attention with whatever suggestions he might have for future interventions. Thus, through continuing observation and feed-back, the social scientist can provide current, on-going and pertinent information to the administrator that will keep him *au courant* with the social processes about which he is making decisions.

DISCUSSION

MARVIN L. ADLAND, M.D. (Rockville, Md.).—Because there is sufficient truth in all the concepts that Dr. Schwartz has presented, I was tempted to confine my discussion to a brief sentence extolling the neat and concise manner in which the author presented the potential contributions of social science and of a well trained sociologist to the problems of a mental hospital administrator. I found I could not confine my contribution to that approbation because Dr. Schwartz's thoughts provoked a number of most disquieting rumblings.

First I found myself becoming angry with myself and my colleagues who are doing institutional work. Those psychiatrists who devote to hospital psychiatry more than the 3 resident training years required for Board examinations soon become part of a broad and respectable history. There are few books on how to run a mental hospital. The philosophy, the traditions, the knowledge of the problems and the patience to meet those problems, have been passed from colleague to colleague, almost in a master to apprentice fashion, over a space of many generations. And now, almost all of a sudden like, we seem to stare around us stupidly, unknowingly, clutching at every closely or remotely allied discipline to give us the answers, to show us our blunders, to explain our motivation and behavior. What does this semi-paralysis of cerebral function indicate? But before I answer let me go on with another general area of rumbling.

This second area is that of my feeling that perhaps many of the sociologists (and other allied disciplines) who come to be a working part of a mental hospital, do so with the attitude of having to change what is going on. Now mind you, I'm all in favor of changing a lot of things that do or don't go on. But when I make this change I want it to be based on my experience and understanding of the life and function of a mental hospital. Now if the sociologist wants to tell me about his impressions of his observations from his particular point of view, that's fine. I don't find myself intrigued by his observations when they are presented from my psychiatric point of view. Now I'm not saying that this is what Dr. Schwartz was trying to do. I am saying that this may constitute one of the dangers in the relationship and to avoid the harm of this danger, we must recognize its presence.

Now the last major area of rumbling inside of

myself was a feeling that if I knew all that Dr. Schwartz was saying about what a sociologist could contribute to my understanding, I'd pull up stakes and go back into general practice. If all the frills of the evening dress of the formal structure were clearly delineated, if all the dirty linen of the informal structure was exposed, if all the strivings and problems of roles and status were in focus, then the hospital wouldn't be worth a damn—it would have no personality, it would be dead. You can't reduce the behavior of people to a concept of "role playing." You can't put the strivings, hurts

and needs of people into words such as status and power. For me that's too mechanical. I don't want that much analysis.

Well, what does this all mean? To me it means that whatever one's relationship to a mental hospital is, it is difficult. Just as difficult as being a part of any community. And when we get anxious, we start scurrying around to get the efficiency experts to help us with time and motion studies. What we forget is that part of being human is knowing that there is anxiety, and that there are things we don't know.

HEALTH INSURANCE AND PSYCHIATRIC COVERAGE

COMPILED BY HENRY A. DAVIDSON, M.D.¹

A symposium on health insurance and psychiatric coverage featured one of the May 14 sessions of The American Psychiatric Association's 1957 Annual meeting. The speakers were:

1. Mrs. Edith Alt, Consultant on Community Resources, to the Health Insurance Plan of Greater New York. Mrs. Alt spoke on Consumer Need for Insurance Protection for Psychiatric Care.

2. Louis S. Reed, Ph. D., Health Economist, U.S. Public Health Service. Dr. Reed spoke on the present practices of health insurance plans with reference to psychiatric illness.

3. Mr. Harry Becker, Staff of New York Blue Cross. Mr. Becker's topic was "Psychiatric Services under Labor-Management Health Protection Programs."

4. Mr. John R. Mannix, Executive Vice-President, Cleveland Hospital Service. Mr. Mannix discussed Cleveland's experience with psychiatric coverage under Blue Cross.

5. Mr. Albert V. Whitehall, Associate Director for Health Insurance, Life Insurance Association of America. Mr. Mannix spoke on "The Problem of Broad Coverage."

These five papers are abstracted below.

MRS. EDITH ALT

Mrs. Alt suggested that the challenge of providing ambulatory psychiatric care for low and middle income groups may well head the list of today's unresolved health problems. The range of "psychiatric" problems is as broad as life itself. Marriage counseling, vocational guidance, trouble in reading, juvenile delinquency, these all might be considered appropriate for psychiatric referral. However, as a practical matter, it seems best to limit the phrase "psychiatric need" to "illness" in the clinical sense. Any systematic method that will bring to consumers the kind of treatment required is bound to have a profound effect upon the practice of psychiatry and contribute to a more productive

use of so valuable a service. Mrs. Alt referred to experience with the Health Insurance Plan of New York. This provides psychiatric consultation service. The subscriber has the benefit, without any financial barrier, of early detection and diagnosis. However, the Plan does not include psychiatric treatment.

Among Plan subscribers, 90% of the heads of families have incomes of less than \$7500 a year and 90% of the unmarried subscribers have incomes of under \$5000 a year. The patients who have been given psychiatric diagnoses here include some really sick people who are still ambulatory. Psychiatrists, whether in clinic or in private offices, say that these people are unrewarding to work with. Other problem cases are: seniles who need supportive care; persons of all ages who require immediate attention to meet emotional crises; a group who, with intensive treatment, could actually avoid hospitalization; some whose emotional needs are interwoven with medical problems (including subscribers with amputations, allergies, peptic ulcers and heart disease) who need integrated treatment and other people whose ability to function is so impaired that they need psychiatric attention to attain self-sustaining levels of living.

Failure to provide psychiatric treatment reinforces the idea that there is something special or different about emotional illness. The exclusion serves to stigmatize mental illness. Other physicians, whose specialties *are* covered, get the feeling that psychiatry must lie outside the pale of medicine.

Only 10% of America's population is in a financial position to "buy" psychiatric care on the traditional "fee for service" basis. Thus 90% of our fellow-citizens must look to the Government or private philanthropy to help them; or they borrow and build up a crushing burden of debt; or they just go without treatment.

The inability of many medical care programs to include psychiatric service is due to the high cost of this service and its

scarcity. However, with the increasing movement from care predominately within hospitals to the newer trend toward community care, we see a significant change. With more knowledge on the part of the consumer, encouraged by reports of shorter treatment periods, and more emphasis on early case-finding we can expect that more people with psychiatric illness will come for treatment and at an earlier point in the illness. Insured families, regardless of income, are more likely to utilize the service than uninsured families in the same financial bracket. Thus, insured persons will have their psychiatric needs assessed at an earlier point.

In Mrs. Alt's opinion, only one plan has been able to include adequate ambulatory psychotherapy. This is the Health Insurance Fund of West Berlin. This program insures 750,000 people. Though focused on the ambulatory patient, this agency also accepts for follow-up, some ex-hospital patients after discharge. The program covers psychosomatic illnesses, psychoses, and psychoneuroses. Both individual and group psychotherapy are available.

How much of a drain is psychiatric treatment on the resources of the fund? This is the problem which seems to trouble insurance carriers here. The answer is 1%. That is, of West Berlin's insured load, 1% are ambulatory patients receiving psychotherapy.

The fund provides for 200 treatment hours for each patient who needs it. Each month they see about 150 new adult patients and from 50 to 60 new children per month in a reception unit. This unit reports that one-third are not treatable; one-third have a good prognosis and one-third are in a borderline category. Those considered "not treatable" are referred back for supportive psychiatric care or social care. The one-third with a good prognosis are generally accepted and the one-third who are considered "borderline" are studied more carefully to determine whether they can be helped.

The waiting period between acceptance and the beginning of treatment is usually about 3 months.

They aim at time-limited psychotherapy, trying to get results in 100 treatment hours. Patients are seen 2 or 3 times a week, to a general maximum of 1½ years. The care-

ful and comprehensive character of their screening seems to be the crux of their plan—that and the "time-limit" aspect of psychotherapy. It cost the Institute about \$180 a year for each patient in psychotherapy.

In this country, current pressures for additional and more available psychiatric services can push us toward government responsibility for all forms of psychiatric care. There is another possibility, more consistent with our evolutionary social process: to work for a partnership of cooperative voluntary effort, government and individual responsibility. In this choice lies the challenge for all of us concerned with the health of our people.

DR. LOUIS S. REED

Dr. Reed pointed out that there are 4 principal groups of health insurance plans in the United States: (a) Blue Cross plans; (b) Blue Shield plans; (c) insurance companies writing health insurance policies; and (d) company and union self-administered programs, cooperative and community plans and private medical group clinic plans.

About a third of the Blue Cross plans provide no coverage for mental, emotional or "nervous" cases; a small group provide coverage until diagnosis has been reached or for not more than 21 days. The remainder provide coverage for periods ranging from 21 days, up to 31 days. A few cover for as many as 70 days and three for up to 120 days. Many plans apply only in general hospitals, not in mental hospitals.

The Blue Shield plans (generally restricted to surgical and in-hospital medical service), usually cover mental illness on the same terms as all other illnesses or conditions.

Commercial insurance policies covering hospitalization, surgical expense, and medical calls almost universally provide the same coverage for mental and emotional as for other conditions. Under "major medical" or "comprehensive medical expense" policies the same is generally true although some policies provide for a lesser degree of reimbursement in mental illnesses if the patient is not disabled or hospitalized.

Most of the independent plans do not pro-

vide coverage of mental or nervous conditions after diagnosis.

Psychiatric illness should be covered by pre-payment plans on the same basis as other illness. The coverage of hospital care in general hospitals for acute mental conditions does not appear to offer difficult problems and would probably not result in major additions to present costs. The trend in prepayment coverage is decidedly toward greater comprehensiveness. If the cost of care in State mental hospitals were also included, it might eventually result in profound changes in the methods of financing this type of hospital care.

Coverage of office and home service for psychiatric illness waits, in any case, on the development of methods of providing office and home coverage of physicians' services generally. Many say that this kind of coverage is simply not feasible on a free-choice basis because of the possibilities of abuse. The problem of keeping costs within a reasonable limit seems particularly difficult with emotional illness, since—with psychotherapy at least—it is hard to specify a limited frequency of visits or a limited maximum duration of therapy.

MR. HARRY BECKER

Mr. Harry Becker called attention to the not-fully recognized fact that today there are no significant groups of persons employed in industry, and who regularly work for others, without some form of hospital-medical protection.
